Asters growing commercially under cloth enclosure. This construction aids greatly in insect control, particularly the leaf hopper, the carrier of Aster Yellows, and reduces to some extent the severity of Fusarium wilt. Asters grown under cloth are superior to those grown in the open.

SUMMARY

1. The aster is deserving of more consideration than is commonly given it. The demand for aster flowers for commercial purposes far exceeds production in Indiana.
2. The importance of securing good disease-free seed of the best varieties can not be over-emphasized.
3. Aster plants should be kept growing in a vigorous manner. Plants once stunted, from any cause, are seldom profitable.
4. Asters are shallow rooted, therefore, successful culture under field conditions is often dependent on irrigation.
5. Greenhouse grown asters are generally superior to field grown. They deserve more consideration as a greenhouse subject.
6. Artificial light supplementing daylight, five hours at night using lamps of as low as 15 to 100 watts (one lamp per 30 feet of bench space) made possible the production of a mid-winter crop of greenhouse asters of excellent quality.
7. Artificial lighting on aster seedlings immediately after germination for from seven to 26 days increased earlier flowering under field conditions as much as two weeks. All varieties do not respond in a like manner to light treatment.
8. Flowers grown for the market should be carefully graded and standardized. This decreases to the minimum the quantity to be handled. Better prices are generally secured.
9. Investigational work for the last six years, with more than 300 aster varieties and strains, reveal that none are immune to Fusarium wilt, although some may show high resistance for one or more years.
10. It is apparent that there are several strains of Fusarium wilt of asters. An aster strain which is highly resistant in one locality may be very susceptible in another.
11. Experimental work substantiates the belief that asters can be grown commercially in specially constructed cloth houses which aid in insect control. Asters grown in cloth houses are superior in quality to those grown in the open.
12. Disease and insect control through prevention is most effective and less costly.

ASTER CULTURE

E. R. Honeywell
Department of Horticulture

INTRODUCTION

Few ornamental plants have been introduced into the United States which have gained greater universal popularity than the China Aster. The main reasons for its popularity are its wide range of color, variety of form, decorative value both as a cut flower and for garden plantings, and its comparative ease of culture. Unfortunately, recent manifestations of disease and insect pests have made the culture of asters a trying problem in many regions. The number of asters now being grown in Indiana by amateur and commercial growers is much less than in preceding years, although the demand for good cut blooms for commercial purposes far exceeds production. The keen interest of amateur and commercial aster growers has aided much in stimulating investigational work to determine ways and means of combating aster diseases and insect pests. More consistent effort is needed, but it is believed that asters can still be produced commercially at a profit if careful attention is given to cultural practices.

EARLY HISTORY

The China Aster (Callistephus chinensis), a native of China, was introduced into Europe about 1731 by R. P. d'Incarville, a Jesuit missionary. At the time of introduction the flowers were single, that is, the rays or ligulate florets were of only two to four rows, which were blue, violet or white. The aster became well known to American gardens about 1800, but it was not until about 1837 that numerous varieties of specified colors were available. In about 1850 development of the central florets became common and varieties of the full-quilled types were highly esteemed. Later developments brought about further changes in form of flower and plant habit until at the present time there are many well-marked races or types, each of which has a wide range of colors.

CLASSIFICATION

Many attempts have been made to organize all aster varieties into definite classes or horticultural groups. However, changes have and are still coming about with such rapidity that it is impossible to construct a satisfactory classification, especially if an attempt is made to include all the recognized groups of the trade. Asters, like many other plants, do not always come true to variety. Oftentimes some hybridization takes place between varieties, thus resulting in hybrids of slight variations in color, form of flower and plant habit. It has also been noted that characteristics in certain varieties change due to environmental conditions such as soil, temperature and moisture; such variations are seldom permanent. It is hoped that the following classification may prove helpful:

Based on Habit of Growth

1. **Tall Pyramidal Asters.**—Plants of dense, vigorous pyramidal habit, flowers borne horizontally; well suited as garden subjects.

2. **Tall Branching Asters.**—Plants of upright spreading habit, flowers borne on long stiff stems, unexcelled for commercial use.

3. **Dwarf Asters.**—Plants may be branching or pyramidal in habit. Flowers are generally small and borne on short stems. Commonly used for dwarf bedding. Many varieties are early flowering and well suited for commercial use.

Based on Season of Flowering

1. **Early Asters.**—Require a short growing season. Should be planted early (March 1) in greenhouse or specially prepared hotbed. Flower about July 15 to August 1. Example: var. Queen of the Market.

2. **Midseason Asters.**—Generally require from three to four weeks longer to flower than the early varieties. More robust in growth, easy to grow. Should be used to extend the period of bloom instead of making later sowing of early kinds. Flower August and September. Example: var. Heart of France.

3. **Late Asters.**—Require a long season to flower. Are very desirable for they bloom when flowers of other species are lacking. Seeds are generally sown somewhat later than for earlier flowering varieties. Flower about September 1 to October 1. Example: var. Ball's White.

CULTURE

The aster is deserving of more intelligent management. No longer is it possible to carelessly sow a package of seed and be assured of excellent rewards for such limited effort. To grow good asters at a profit requires skill and close attention to modern practices. This involves more consideration to improved varieties, soil preparation and planting, cultivation, irrigation, marketing, and insect and disease control.

Seed

The importance of securing good seed cannot be over-emphasized. It is very essential that flowers come to marketable maturity early, that they be uniform in size and character, and that they be as free from disease as possible. The small saving made by investment in cheap or inferior seed is usually lost many times over in lessened value of the crop. No one can afford to risk his crop for so small a saving.

Early Asters

Early asters are generally considered to be more profitable than later sorts providing greenhouse or hotbed facilities are available for starting the plants. Under these conditions the seeds are generally sown in a shallow flat or in a specially prepared bench or heated frame. Early March is considered the best time for seed sowing providing the plants can be kept growing in a vigorous manner. Asters allowed to become pot-bound or stunted in any way are useless. They may flower early, but will be of little commercial value.

Soil for Seed Sowing.—As a rule aster seeds germinate freely and are viable; nevertheless, it is economy to have the soil finely pulverized and in the best physical condition. A sandy loam is very suitable; however, humus in the form of peat or well decayed manure often proves beneficial. Organic matter which is not well decayed is usually detrimental to the seed. A soil mixture composed of one part sand, three parts loam and one part peat or leaf mold has given excellent results.

Sowing.—The commercial practice among most growers is to sow aster seeds in flats, although many prefer the bench method. The most satisfactory method largely depends on available facilities. In either case the principles of planting are similar. Good drainage is essential. Proper drainage may be secured by placing a layer of coarse soil, sand or gravel in the bottom of the flat or bench before the prepared soil is added. The planting soil must be perfectly level and slightly compacted. The advisability of sowing seeds in rows or scattering them uniformly in the flat or bench and covering to an even depth of one-fourth inch is a matter of opinion. In most cases it seems best to sow seeds in rows two to three inches apart rather than broadcast. By this method they are more easily weeded and cultivated and are generally planted at a more uniform depth.

The soil should be thoroughly watered after seed planting and at intervals when needed, care being taken that seeds are not washed about. Frequent light waterings are undesirable as they cause crust formation of the soil which will interfere with the ease of germination and will later cause shallow root formation.

The optimum temperature for seed germination is about 65° F. Some bottom heat is helpful. As soon as germination is complete the young seedling will respond best to a temperature of about 60° F. The lowering of the temperature at this stage of development greatly stimulates the plant to a stronger, healthier growth. The required time for germination will largely depend on culture, season, variety and atmospheric conditions. Germination should be complete in seven to 10 days.

Transplanting.—As soon as two true leaves have formed the seedlings should be pricked off into flats or potted. Under proper cultural conditions about two or three weeks are required for the plants to reach this stage of development. It is really a critical stage in their growth for at this time they are very susceptible to the damping-off fungus.

The soil used for transplanting should be somewhat richer than that used for seeding and may contain more well decomposed organic matter without injury. The soil should be thoroughly moist, but not sticky. Plants set in flats should be placed about 1½ inches apart in rows 2 inches apart. The flats should be at least 2½ inches deep and of a convenient size. All plants should be pressed down firmly and evenly. As soon as the flat is filled it should be placed on a level bench or prepared bed and the plants thoroughly watered. The plants should be shaded during bright days until they become well established. Proper watering and air circulation are important factors. A temperature of 55 to 60° F. is most desirable at this stage.

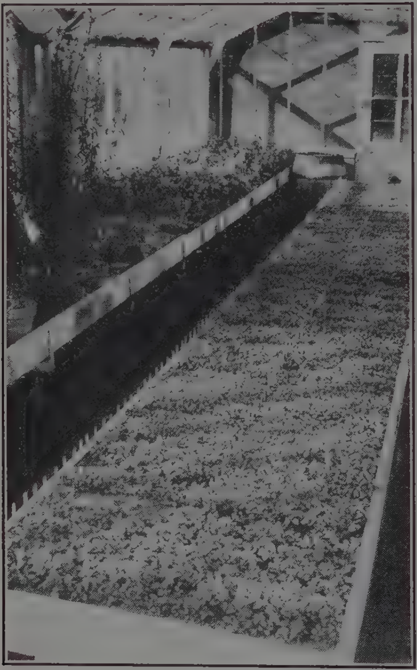

Figure 1. Many growers prefer to start aster seedlings in benches rather than in flats, as it is more economical of space, time and labor and more uniform conditions are assured. This is especially true if many varieties are grown. In the above illustration 175 varieties are being grown for experimental purposes.

A few commercial growers make it a practice of potting asters for field culture. Two and one-half inch pots generally provide sufficient soil to nourish a healthy growth for field planting. It is generally preferred to grow asters in flats rather than in pots for it conserves time, labor and space.

Hardening. — Asters grown in flats or pots should be well hardened off before transplanting to the field. The most satisfactory way to do this when the plants are grown under greenhouse conditions is in cold frames. The temperature should be lower and the plants should be watered less frequently. This change should be gradual until the plants become accustomed to outdoor conditions. A few hours prior to setting the plants in the field they should be watered heavily so that the plant tissue will contain all the water possible. Plants which have been hardened off properly become sturdier and will endure the sudden check due to transplanting.

Preparation of Field Soil.—Asters are not considered as being particular to soil type as long as the soil is kept in good mechanical condition. Early asters, however, have a short growing season; therefore, it is important that conditions be made as favorable as possible for their rapid growth. A medium sandy loam with an abundance of well decomposed humus and thorough preparation gives best results. Moderate applications of barnyard manure (10-16 tons per acre) applied the previous year and supplemented with chemical fertilizers are known to give good yields. It is important that no fresh manure be applied just previous to planting. The commercial fertilizers required depend largely on the character of the soil, previous fertilization and crop rotation. On sandy loam soils a 5-10-5 or 4-8-4 fertilizer mixture, or any similar mixture high in phosphorous, applied shortly before planting at the rate of 500 pounds per acre should give good results.

The advisability of liming aster soils is a matter of question. Excellent yields of asters have been known to grow equally well on slightly acid and on sweet soils. It is true that lime has a beneficial effect in making plant foods available, but the practice of dusting lime about the plants during their growing period is not believed necessary. In general, a soil which is congenial for asters is one that contains abundant plant food and organic matter and is well drained. Frequent cultivation and weeding are points which should not be overlooked.

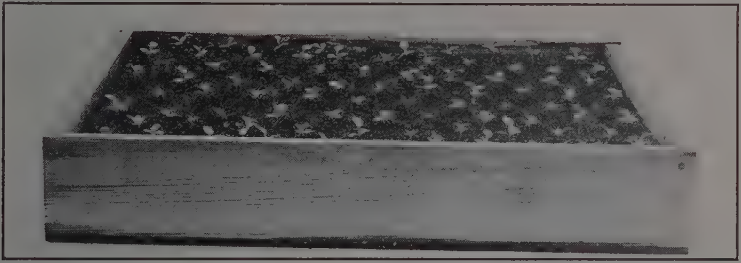

Figure 2. Aster seedlings should be pricked off (transplanted) into flats of convenient size as soon as two true leaves have formed.

Planting.—Early flowering asters should be transplanted to the field as soon as all danger of heavy frost is past and the soil is properly prepared. Under normal conditions May 1 to 20 is considered safe in Indiana. Regardless of whether the plants are grown in flats or pots it should be remembered that transplanting is more or less of a checking operation and the check is directly proportional to the root injury. The advisability of having the soil about the plants moist when removed from the pots or flat is a desirable feature. Watering the newly set plants and firming them well is also extremely important. Plants should be set in the field but slightly deeper than they grew in the pot or flat. Special care should be given that the crown is not deeply covered. A trowel is the most satisfactory tool for planting. Plants respond best if set out in late evening or during cloudy weather.

Planting Distance.—The distance and method of setting plants largely depends on varieties grown, method of cultivation and available area or size of field. Many of the early flowering strains, as Queen of the Market, require less room than plants of the larger flowering varieties. Many growers prefer close planting and rely on hand cultivation. The most common practice in field culture is to set the plants six to 12 inches apart in rows 18 inches apart.

Where plenty of land is available some growers prefer to plant in rows three feet apart, making it possible to use a horse or motor power for cultivation. Another method in common use is to plant in rows about one foot apart, omitting each sixth or seventh row to be used as a walk. Such a method utilizes small areas to best advantage but makes hand cultivation necessary.

Recommended Varieties and Strains (Early)*

Variety Name or Strain	Plant and Flower Characteristics	Colors
Lavender Gem	Full double flowers, borne on strong stems of medium length. The petals are gracefully curled and twisted. 20 inches.	True lavender.
The Royal	Plants are vigorous and very productive. Low branching habit. Stems medium to long. A good general purpose aster. 24 inches.	White, scarlet, white and lavender.
Queen of the Market	The leading early strain of asters. Used extensively for greenhouse culture. Stems are of medium length. Plants are of graceful habit. 18 inches.	Pink, scarlet, lavender and white.
Early Wonder	Very early flowering. Flowers large and full, of the Comet type. Plants medium vigorous. 20 inches.	White, rose, light blue and lavender.

*Varieties which have given good results under experimental conditions.

Midseason and Late Asters

Although early flowering asters of good quality are greatly prized when cut flowers of many other species are lacking the importance of later flowering sorts should not be overlooked. The midseason and late varieties of asters are generally larger flowering and of better quality with longer stems than the early strains and should be used to extend the flowering season instead of making later sowings of the early kinds. Under ordinary cultural conditions more satisfactory results are obtained from the later sorts because they require less attention and are easier to grow.

Seed Sowing and Planting.—Seeds of the midseason and late flowering asters are generally sown during the latter part of March and early April under greenhouse conditions or in specially prepared seed beds such as hotbeds or well protected cold frames. In case manure is used to furnish the necessary heat in hotbed preparation it is important that the manure be well packed and covered with at least three inches of good rich loam. A prepared soil consisting of one part sand, two parts loam and one part peat or leaf mold placed one inch deep on the rich loam soil and properly firmed and leveled will provide a good medium in which to sow the seed. It is essential that the soil be of sufficient depth to prevent the roots of the seedlings coming in immediate contact with fresh manure. Asters planted in hotbeds and cold frames should be planted deeper than in seed flats under greenhouse conditions. Seeds planted in drills three to four inches apart to a depth of one-half inch should give good results. One ounce of seed should be sufficient to plant from 100 to 150 feet of drills. There are approximately 10,000 seeds per ounce.

The seed bed should be well protected from wind and cold and should be kept as near the optimum growing temperature as possible. During warm days when weather permits the sash should be partly removed so that plenty of air may be available thus enabling the plants to become accustomed to gradual changes.

Under favorable weather conditions seeds of asters may be sown in the open ground during the latter part of April and early May. Usually, however, it is more desirable to sow all kinds of aster seeds in specially prepared seed beds in suitable soil and transplant the seedlings once before planting them in the garden or field.

Recommended Varieties and Strains (Midseason and Late)*

Variety Name or Strain	Plant and Flower Characteristics	Colors
American Astermum	An attractive aster of the Comet type. Plants are of upright growth, free branching. 24 inches.	White, rose, pink and dark lavender.
Ball's White	A splendid large flowering aster of good shipping quality.	Pure white.
California Giant	Very late flowering. Plants unusually vigorous, flowers large. 30 to 36 inches.	White, deep rose, light blue and purple.
Giant Crego	Flowers of immense size borne on long strong stems. The petals are attractively twisted and curled. Plants are strong branching. 24 to 30 inches.	Shell pink, crimson and lavender.
Heart of France	A striking color of ruby red. Shows high resistance to aster wilt. 24 inches.	Ruby red.
Ostrich Feather	A desirable large feather type aster which produces in great abundance. The flowers are borne on long stems which makes them excellent for cutting. 24 to 30 inches.	White, soft pink, crimson, light and dark blue.
Peerless Pink	Strong, sturdy habit of growth. The flowers are of enormous size. Globular in shape. 24 to 30 inches.	Shell pink.
Sensation	Flowers double and incurved, resembling a dahlia. The plants are of free branching habit. 18 to 24 inches.	Cardinal red.
Moreton Pink	Plants of the giant branching type. The flowers are large, well formed and freely produced on long stems. 24 to 30 inches.	Clear pink with a salmon sheen.

*Varieties which have given good results under experimental conditions.

Planting is best done during the cooler portion of the day or when cloudy. Plants which are set out dry during the heat of the day are often permanently injured. During hot dry weather all plants should be properly watered when set. The water should be applied about the plant before all the soil is added. After an interval of perhaps one hour the remaining soil should be drawn in about the plants and firmed; this will prevent excess baking of the soil.

Midseason and late flowering asters are generally planted 12 to 15 inches apart; this is especially true of the late branching types which require more space than the early flowering kinds.

Preparation of Field Soil.—The soil and its preparation for midseason and late flowering asters should be similar to that described for early asters. It is of common belief, however, among commercial growers that the later flowering asters will respond best to soils which are somewhat heavy since they are cooler and more retentive of moisture. The amount of manure and commercial fertilizers required to produce a good crop will be less for the later asters because of their longer and more favorable growing season. The necessity of stimulating quick, rapid growth and maturity is of less importance in the late flowering kinds. The importance of early plowing and frequent cultivation to destroy weeds and to put the soil in the best physical condition before planting are factors of major importance.

IRRIGATION

Asters do not have a deep root system; therefore, successful culture under field conditions is often dependent on irrigation. The most profitable method of applying water largely depends on source of supply and available equipment. Uniformity of water distribution is very important. For this reason the overhead sprinkling system is preferred by most growers.

Irrigation may be used to good advantage as an aid in transplanting. The soil should be thoroughly moist before planting and gently watered afterwards. This enables the plants to become well established during their early growing period. Under conditions where the overhead irrigation system is used it is important that all aster plants be well mulched as soon as the plants become well established and that cultivation be discontinued. A clean straw mulch is considered best. If a straw mulch containing considerable manure is used it should not come in direct contact with the plants. Under ordinary conditions evening or night waterings promote best growth. Under no condition is it advisable to apply water during the heat of the day in full sunlight. Watering during midday results in scalding and promotes a weak, soft growth and flowers of inferior substance and quality.

GREENHOUSE CULTURE

Although asters are commonly grown to maturity under greenhouse conditions they are not in the usual sense considered as a forcing crop. The time or season of flowering is not greatly influenced by the time of seed sowing. Under experimental conditions asters planted during the months of March and April come into bloom and produce flowers of more uniform size and quality than those planted at monthly intervals from October to February. Thus, sowing earlier than March or April does not seem advisable.

Commercial florists who have greenhouse space available during the summer months can grow asters at a profit providing special attention is given to cultural methods. Greenhouse grown asters are generally superior to field grown plants. They are less likely to be damaged by insects. They are less susceptible to injury due to dust and rains; the stems are usually longer and the flowers are larger and of better lasting quality.

Sowing

Asters grown for greenhouse culture should be started in late March or April depending on the availability of greenhouse space. Method of seed sowing and general culture should be followed as described for early asters (page 5). Irrespective of the source of seed or variety grown all seed should be thoroughly disinfected before planting (page 15).

Soil Preparation

There is a wide difference of opinion regarding the comparative merits of raised benches and solid beds for greenhouse asters. In general, solid beds are preferred.

A naturally deep, well drained, friable soil is considered best. Many growers have had profitable results growing asters in soil in which other crops such as carnations, snapdragons, sweet peas and calendulas have been grown. It should be remembered, however, that to produce asters of good quality a congenial environment is essential, including a soil of excellent physical condition and well supplied with readily available plant food, so that a rapid and uninterrupted growth is assured.

Planting

Long narrow beds or benches not exceeding five feet in width are most desirable for asters. The plants should be set as soon as they have developed to a convenient size. About six or eight weeks after seed planting is required to have good vigorous plants for setting. Plants grown in flats are equally as good as those grown in pots providing they have been properly cared for and carefully removed from the flats.

Aster plants are sometimes set 10 x 12 or 12 x 12 inches apart and some growers prefer setting them 10 x 10 or 6 x 10 inches. Most growers use a planting distance of 10 x 10 inches. The type or varieties of plants grown should be the determining factor; early asters may be set much closer than the late branching sorts. Care should be exercised to firm the soil uniformly about each plant and water thoroughly.

Temperature and Ventilation

Asters prefer a cool temperature; therefore, the house temperature should be as carefully regulated as possible. The vigor of aster plants depends largely on correct temperature. It requires some shading to keep the house temperature to the minimum during the summer months. The atmosphere should be fresh and sufficiently moist. Syringing the foliage and dampening the walks on sunny days should be practiced. Asters not supplied with an abundance of fresh air are likely to make weak, soft growth, be of poor quality and color and be more susceptible to insect and disease attack.

Cultivation

Thorough preparation of the soil before the plants are set is the most important part of the cultivation of greenhouse asters. During the growing season, however, the surface soil should be stirred frequently. This keeps the weeds in check and also provides for aeration of the soil and assists in regulating proper moisture conditions. Deep cultivation is unnecessary and should be avoided as there is great danger of disturbing the roots. Cultivation should cease as soon as flower buds appear. A light mulch of well decayed manure or peat applied during the early growing season generally gives good results.

Watering

Asters require considerable water, but it must be applied with care. Excessive applications of water cause unfavorable plant growth and the plants are more susceptible to disease. This is especially true of plants grown in ground beds. Watering in early forenoon seems to give most satisfactory results. At no time during their growth should the plants be allowed to become dry.

Recommended Varieties and Strains* (Greenhouse)

Variety Name or Strain	Plant and Flower Characteristics	Colors
American Astermum	An attractive aster of the Comet type. Plants are strong, of upright growth, free branching, medium early.	White, rose, pink and dark lavender.
Purity (Improved purity)	A good commercial strain of symmetrical habit. Early.	White
The Royal	Plants are vigorous and very productive. Low branching habit. Stems medium to long. Medium early.	White, lavender and deep rose.
Queen of the Market	The leading early strain of aster. Used extensively for greenhouse culture. Stems of medium length. Plants are of graceful habit. Early.	White, pink, lavender and scarlet.
Early Wonder	Very early flowering. Flowers large and full, of the Comet type. Plants medium vigorous.	White, rose, light blue and lavender.

*Varieties which have given good results under experimental conditions.

Artificial Illumination

Midwinter crops of asters of excellent quality have been grown with artificial light supplementing daylight. Five hours of added light from 15 to 100 watt lamps per 30 feet of bench space gave excellent results. Indications are, with the variety Heart of France, that it is necessary to light the plants from an early stage until the flower buds appear in order to produce good quality blooms. Although lighting for a shorter period (40 days) immediately after germination has been successful in inducing very early flowers, the blossoms were often abnormally formed and the stems short.

With a number of other varieties of asters, including Early Royal, Queen of the Market, Comet, King and American Branching types, earlier flowering was general, and large, long stemmed flowers were produced as contrasted with small dwarf blossoms from plants grown without additional light. It may be noted especially in this connection that different varieties of asters give different responses to the same conditions of lighting. Therefore, it is difficult to predict the exact degree of success that may be obtained without using artificial light over any particular variety.

By using artificial light over seedlings for field planting for from 7 to 26 days immediately after germination an earlier crop was produced. Results of this investigation indicate that the crop was on two weeks earlier, the flowers commanding a higher price by reason of their earliness and the cost of cultivation being reduced since disbudding, watering and insect control measures were materially lessened. Early Royal Purple and Shell Pink were the varieties used for experimentation.

MARKETING

To grow a good crop of asters is not sufficient. They must be marketed at a profit before they can be considered as a paying investment. The ability of a grower to properly market this product requires judgment and skill. It is not an uncommon sight to see asters of the very best quality bunched and handled in a way that they have little or no sale value, while flowers of inferior quality attractively bunched meet with ready sale. It is true that asters vary greatly in shape, color, size and quality; nevertheless, grading reduces the cost of marketing by decreasing to the minimum the quantity of flowers that are to be handled. Graded and standardized flowers also bring higher returns and generally make satisfied customers.

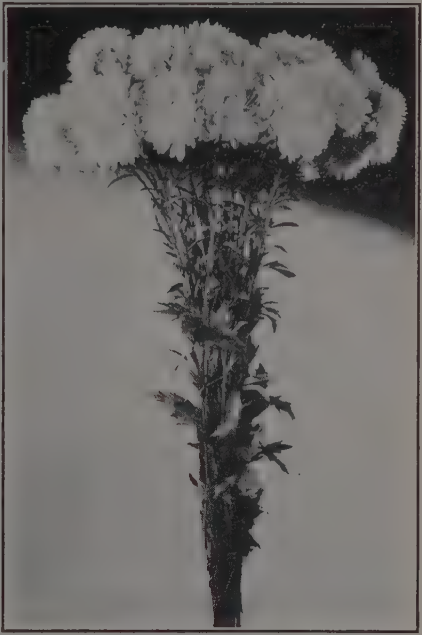

Figure 3. A commercial bunch of 25 asters. Grading reduces the cost of marketing by decreasing to the minimum the quantity of flowers to be handled. Graded and standardized flowers bring higher returns.

Asters should be graded according to length of stems, color of flowers and quality of blooms. It is considered good commercial practice that each bunch contain 25 blooms. The leaves on the lower six or eight inches of the stems should be removed and each bunch be neatly tied. The flowers should be cut early in the morning or late evening when the stems are turgid. Flowers that are about two-thirds open are in the proper stage of development for cutting. As soon as the flowers are cut they should be placed in deep containers of fresh water and stored in a dark cool room free of drafts for a period of several hours before being used or packed for shipping. Flowers packed for shipping should be turgid, but free of all excess moisture. The best colors for commercial use are white, light and dark pinks and light lavenders.

DISEASES

Aster Wilt (*Fusarium conglutinans*, Wr. *var. callistiphi* Beach).

In geographical distribution aster wilt has been reported throughout the main aster growing sections of the United States, Canada and several other countries. It is probably the most widespread and destructive disease known to asters. The disease is caused by a soil-inhabiting fungus, which gains entrance through the roots and continues growth upward through the vascular system, thus causing a sudden wilting and dying of the plants. The disease is seed-borne and is able to live saprophytically in trash and soil for a period of many years even in the absence of the host plant. Asters in all stages of growth are susceptible to attack.

Symptoms.—The most conspicuous symptom on seedling plants is very similar to and hardly distinguishable from the ordinary "damping-off" disease. Damping-off, however, attacks the plant at the surface of the soil while the wilt organism attacks just below the soil surface.

The first distinguishable characteristic common to plants after the seedling stage is the greatly reduced and blackened root system. Upon examination it may be found that the cortex of the main root is nearly rotted away. A reduction of the roots generally occurs before there is any symptom of wilting or stunting of the plant.

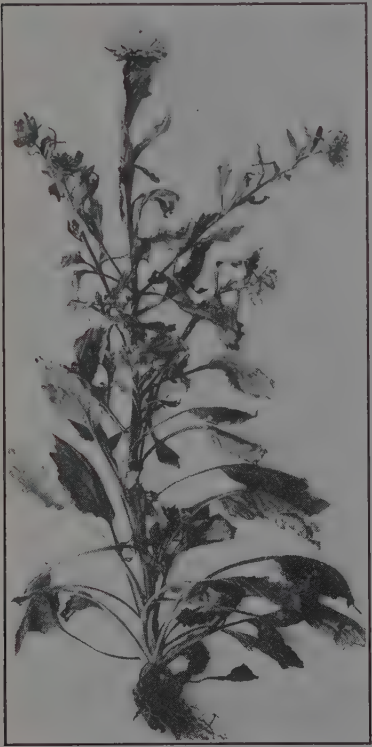

Figure 4. Aster wilt. The fungus first attacks the roots of the plant and advances up the stem, frequently causing the entire plant to suddenly wilt from top to bottom. The root system is greatly reduced and blackened. Plants succumb more rapidly during hot dry weather.

Plants which have been able to endure the disease or have not been attacked until they have gained considerable size show a peculiar type of leaf wilting. The lower leaves wilt but remain attached to the plant. The diseased area is not evenly distributed over the leaf but generally shows effect of wilting on one side. The diseased area becomes darkened and increases in size, causing the leaves to curl. Leaf wilting generally first occurs on one side of the stem, but soon encircles the plant.

The disease progresses very rapidly after once gaining entrance. The first symptom on the stem is an irregular brownish streak generally on one side, which later develops around the entire circumference. This peculiar darkened or black streak may first appear just above the soil surface or it may develop on some of the larger branches or stems. The entire stem becomes blackened during the later stage of development. In case of excessive shade and dampness, either under field or greenhouse conditions, the blackened area of the stem may become covered with a grayish-pink growth with masses of spores.

CONTROL

Prevention is the best method of control. Inasmuch as the disease is known to be transmitted by the seed and through the soil it is obvious that seed disinfection, crop rotation and soil treatment should be practiced.

Seed Treatment.—Aster seed should not be planted until first treated with some well known disinfectant. This simple but neglected operation is often the limiting factor in successful aster culture. Mercuric chloride (corrosive sublimate) in solution used as follows has proved satisfactory:

1. Place the seed in a cloth bag and soak in clean water at a temperature of 100° F. for 30 minutes. Allow excess water to drain from bag.

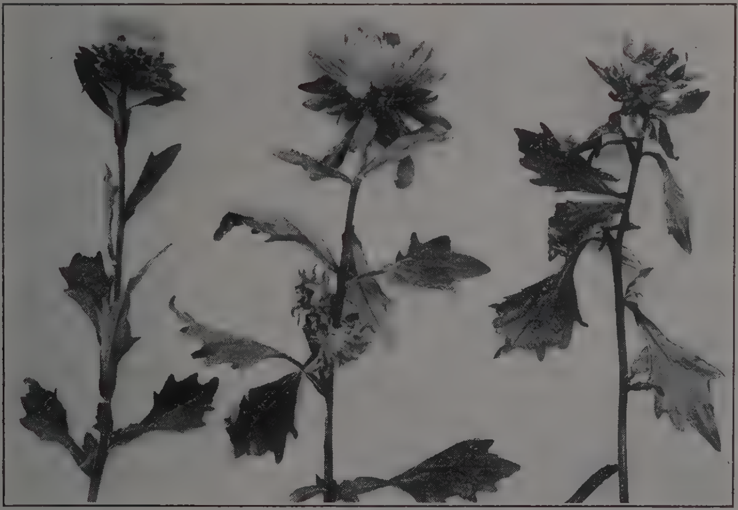

Figure 5. Aster wilt. The leaves first become a sickly yellowish green, wither, curl and finally become black. They generally remain attached to the stem. The flowers are ill-formed and blackened, having a burnt appearance.

2. The bag, containing seed, is then immersed in a 1 to 1000 solution of mercuric chloride (equivalent to one ounce to seven and one-half gallons of water) for 30 minutes at a temperature of 100° F. Allow excess water to drain from bag.
3. The seed is then washed for several minutes in cold running water, immediately removed from bag and spread out on paper or cloth in an ordinary heated room for a period of 24 hours to dry.
4. Plant seed immediately or store in a dry place.

Soil Treatment.—*Crop Rotation*—Asters should not be grown continuously in the same soil. The disease organism is known to live over in infested soil for many years. Change of seed beds and crop rotation are important means of control. The addition of fresh manure or heavy applications of nitrogenous fertilizers greatly increase the severity of the disease regardless of soil types.

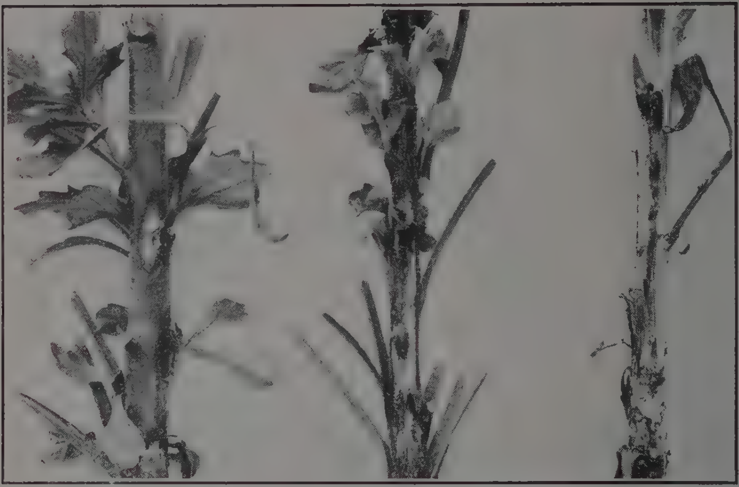

Figure 6. Aster wilt. The first manifestation on the stems is the appearance of a dark brown irregular streak. In case of excessive shade and dampness, the blackened area may become covered with a grayish-pink growth with masses of spores.

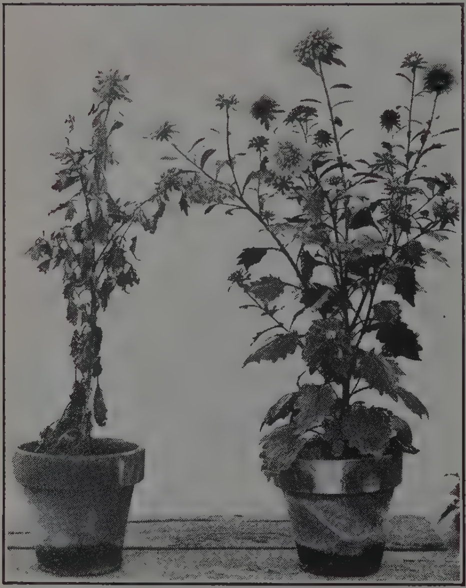

Figure 7. Aster wilt. Diseased and normal aster plants showing the effect of steam soil sterilization. The soil in which the normal plant was grown was sterilized for five hours at 180° F. Soil in each pot was similarly treated except for sterilization.

Steam Sterilization.—Steam sterilization of seed beds, flats and greenhouse soils is an effective and satisfactory method of control providing proper equipment is available and precaution is taken to eliminate all danger of reinoculation. In order to avoid reinoculation only treated seed should be sown and care taken to avoid tracking soils which may be diseased. Uniform steaming of soil for five hours at a temperature of 180° F. has given satisfactory results.

Formaldehyde. — Formaldehyde used at the strength of one pint (40 per cent formaldehyde) in 15 gallons of water, applied at the rate of one gallon per square foot of soil, will give good results. It is important that the soil be in good physical condition before the solution is applied. The soil should then be covered with paper or burlap for one week in order that the fumes may be retained. The soil should be permitted to dry out, then loosened and thoroughly aerated for a week before planting. Seed flats and pots may be treated with formaldehyde by thoroughly soaking. All tools should be treated with the same solution in order to prevent spreading of the disease.

Shading.—Severity of attack is greatly stimulated by high soil temperature. Aster plants grown in alternate rows with corn or some other tall growing crop are less severely attacked during periods of high temperature than plants grown in plots to themselves. Greenhouse and cloth house grown plants that receive some shade are also generally less severely affected than those that receive no shade.

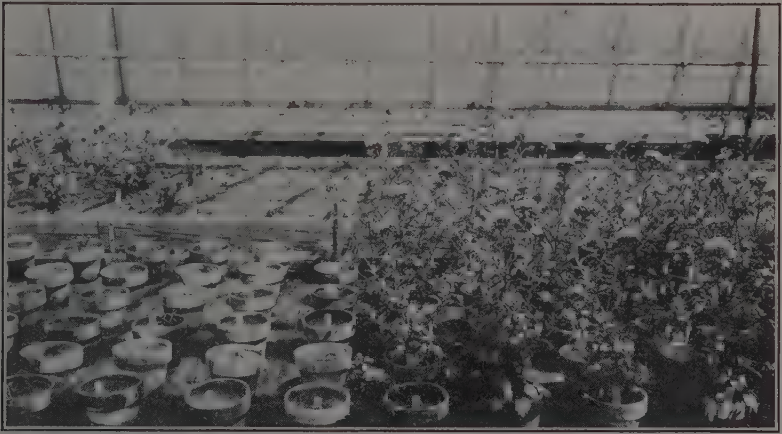

Figure 8. Aster wilt. Seed selections from plants that show resistance to aster wilt is an important means of control. Plants in pots to the right were of a selected strain of Queen of the Market. In the pots to the left were plants of an unselected strain of Queen of the Market. All plants were potted in infested soil.

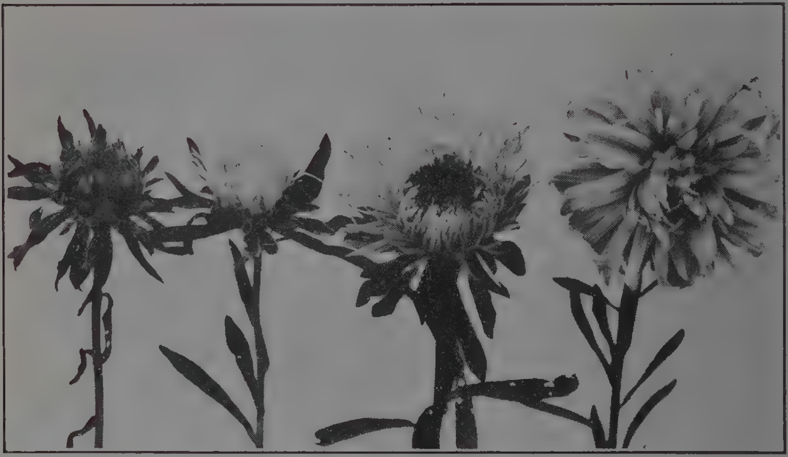
Seed Selection.—Although all varieties of asters are susceptible to aster wilt, individual plants often show considerable resistance. It is apparent that progress is being made in selecting strains that are highly resistant in many localities, although there are none on the market at the present time that are immune. Aster strains which show high resistance in one locality may be very susceptible in another. It has also been noted that a strain which is resistant in a certain locality for one or more years may be very susceptible the following year. Recent investigational work substantiates the theory that there are several strains of the Fusarium wilt organism. Seed selection from plants that show high resistance is an important means of control. All aster growers should practice seed selection.

ASTER YELLOWS (Virus).

Next to aster wilt, yellows is the most destructive disease of the aster. Although "aster yellows" and "aster wilt" are entirely different they are often confused. The yellows disease is known to be transmitted from plant to plant by a small leaf hopper, *Cicadula sexnotata*. The virus overwinters in many common biennial and perennial host plants and is spread each spring from these plants by the leaf hopper.

Symptoms.—The first common symptom to be observed on young infected plants is a slight yellowing along the veins of the leaves. This symptom is commonly referred to as "clearing of the veins." As the disease becomes more severe the entire plant becomes stunted and yellow and an unusual number of secondary shoots develop causing the plant to become very bushy and upright. The secondary shoots are generally spindling. The flowers are abnormal and curiously deformed. Irrespective of the normal color of the variety, the flowers are often a sickly yellowish green.



(Courtesy E. B. Mains)

Figure 9. Aster flowers affected with "yellows" are often dwarfed and curiously formed. Irrespective of the normal color of the variety the flowers are generally a pale green color, although a portion of the flowers may be of normal color. In the above illustration the flowers are all of the same variety. A normal flower is at the right.

Control.—It is obvious that this disease can best be checked by controlling the leaf hopper and destroying the host plants. All weeds in close proximity to aster plantings should be destroyed. Periodically spraying with some form of nicotine or Pyrethrum dusts or sprays will aid greatly in leaf copper control. (See page 20.) All infected aster plants should be destroyed by burning as soon as discovered.

Recent experimental work indicates the possibility of growing asters satisfactorily in specially constructed cloth houses which eliminate the attack of the leaf hopper, the carrier of aster yellows. In some localities these houses have been constructed and asters grown successfully and profitably on a commercial basis. These houses not only aid in insect control but aid greatly in reducing the soil temperature, thus lessening to some extent the severity of aster wilt.

RUST *(Coleosporium solidaginis)*.

Symptoms.—This disease, although common, rarely causes serious injury in Indiana excepting in cloth houses. It is easily recognized by the orange-colored pustules on the under sides of the leaves.

Control.—All infected plants should be pulled out and burned as soon as discovered. Spraying the plants with a good fungicide such as Bordeaux mixture or dusting with special dusting sulfurs are probable means of control.

DAMPING-OFF *(Pythium de Baryanium).*

This disease affects plants during the seedling stage, causing the stem to collapse and rot off at the soil surface. The disease usually occurs in seed beds and flats where the soil is wet, the temperature high and where plants are crowded.

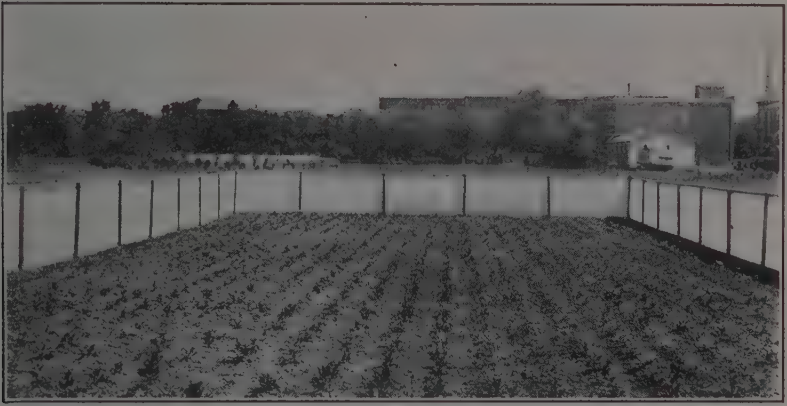


Figure 10. Cloth barriers constructed to a height of 40 inches are not sufficient to give full control of aster yellows. Such a construction, however, aids greatly in the control of blister beetles and tarnish plant bugs.

Control.—The seed bed should be watered only when needed. Soil sterilization by heat before planting is a good method of control. Formaldehyde dust used three ounces per square foot of soil in seed beds, thoroughly incorporated into the soil to a depth of three inches and seeds planted immediately, gives good control. Prepared soil for filling seed flats treated with six ounces of formaldehyde dust to each cubic foot of soil thoroughly incorporated and seeds planted immediately has given good results.

Another good control measure is to mix red oxide of copper with the seed using sufficient dust to thoroughly cover each seed. This dust is very fine and sticky and relatively small quantities will suffice. Plant the seed when desirable after treatment.

INSECTS AND ALLIED PESTS

Blister Beetles.—Many garden plants, particularly the aster, are attacked by blister beetles. These beetles are a half to three-quarters inch long, long-legged, very active and varying from black to gray or black and yellow striped. They frequently appear in large numbers the latter part of June and during July and are usually destructive to the flowers, but frequently destroy the foliage as well.

Control.—Dust plants when dry, preferably during the warm parts of the day, with dusting grade of calcium or barium fluosilicate diluted with equal parts of flour.

Tarnished Plant Bug.—The tarnished plant bug is an active, rather inconspicuous, brownish insect not over 1/5 inch long. It is a sucking insect which attacks the young shoots and especially the buds of flowering plants such as aster and chrysanthemum. The attack, especially when directed at the buds, results in deformed or dwarfed flowers. The insect passes the winter as an adult and breeds primarily on weeds, especially whitetop.

Control.—Clean cultivation and the elimination of the weed hosts are among the most important practices in the control of this pest. Contact sprays are of little value against the adult because of its activity and hardiness against insecticides. A cheesecloth cover over the plants is recommended. In the home garden plants should be dusted with tobacco or pyrethrum dust.

Root Aphids.—Asters are frequently attacked by root aphids or plant lice which may cause the plants to die outright, but usually results in a stunting or yellowing of the plants. Two species of aphids may be responsible, one a bluish-green aphid clustered on the roots or aphids with a covering of white floculent material. The presence of ants, which care for aphid eggs during the winter and carry the aphids from plant to plant during the growing season, is a good indication of aphid infestation.

Control.—Ground to be planted to asters should be plowed or spaded early in the season and the ground kept thoroughly cultivated between the time of plowing and planting of asters. If aphids appear in spite of these precautions the only control is the use of a nicotine sulphate solution (1¼ teaspoonfuls to a gallon of water in which a cubic inch of soap has been dissolved), applying a half teacup to plant, first cupping out the soil around the base of the plant to hold the liquid.

White Grubs.—The curled white worms with brown heads are the immature stage of the common May beetle or June bug. These larvae feed on the roots, cutting them off so that the plants can be easily lifted from the soil.

Control.—Avoid grassy and weedy ground for asters. Where a rotation is practiced use clover the year preceding asters. Carbon bisulphide injected into the soil will protect individual plants.

Red Spider.—These are tiny mites, varying in color from yellow to red, which infest the under leaf surfaces and frequently become destructively abundant on garden and greenhouse asters. They are sucking animals and cause a whitening of the surface, especially along the leaf veins. Later the leaves turn yellow and drop.

Control.—Frequent and forceful syringing with water is an excellent preventive. Colloidal sulphur or selenium sulphide used as directed by manufacturers are excellent controls.

Thrips.—The adult is pale to dark brown and 1/16 inch in length when mature. The young are yellow and usually remain in a concealed place. They have rasping and sucking mouth parts and cause a whitening or russeting of the foliage.

Control.—In greenhouses regular fumigation with calcium cyanide or nicotine is effective in controlling this pest. Where spraying is necessary, weekly applications, using one ounce of 40 per cent nicotine sulphate to four gallons of water in which four cubic inches of soap have been dissolved, is effective. A forceful spray is essential and treatment should be made early and before conspicuous injury is observed.

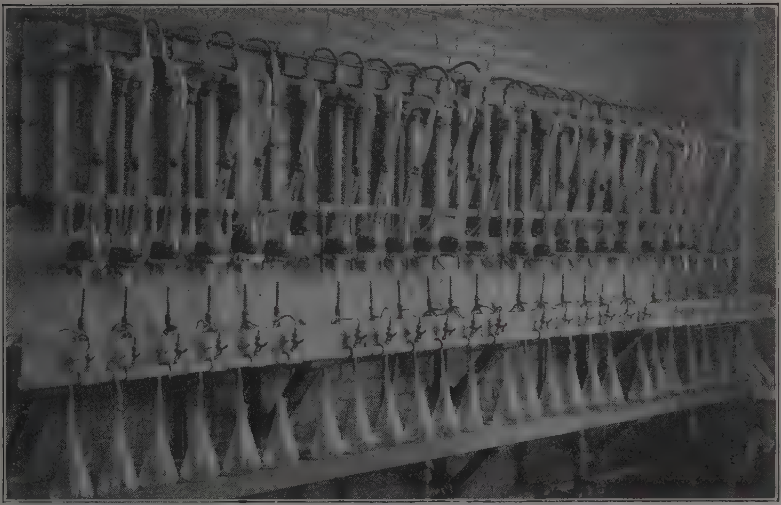
Leafhoppers.—Very small greenish insects which jump and fly about when disturbed. They live on the undersurfaces of the leaves and the immature individuals run quickly to seek the shaded side of the leaf when the leaf is turned over. It is not likely that these sucking insects are directly important, but indirectly they are serious pests since the species commonly occurring on aster (*Cicadula sexnotata*) is the carrier of aster yellows.

Control.—We have no positive evidence that spraying with Bordeaux mixture will control this leafhopper as it does the potato leafhopper. Spraying with one of the standard pyrethrum extracts or dusting with pyrethrum dust should be effective. Clean cultivation of areas around the aster plantings, eliminating such important carriers of aster yellows as fleabane (*Erigeron* sp.), will be a great aid. Screening of aster plants as for the tarnished plant bug will also protect the plants.

UNIVERSITY ARIZONA

Circular No. 201 March, 1934

COMMERCIAL FEEDING STUFFS



Protein Analysis is of prime importance in determining the value of commercial feeding stuffs.

UNIVERSITY OF ARIZONA LIBRARY

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

This circular contains a condensed report of commercial feed inspection in Indiana for the year 1933 and includes additional information pertaining to the Indiana Feeding Stuffs Law and to the composition of feeding stuffs.

Based on the sale of tags it is estimated that 322,318 tons of commercial feeding stuffs with a retail value of $10,373,772 were sold in Indiana in 1933. The inspectors of the State Chemist Department secured 2,592 samples, or approximately one sample for each 124 tons of feed sold in the state.

Of the 2,592 samples collected 461 were found to be incorrectly guaranteed and 296 were classed as being seriously deficient or misbranded. Shipments not tagged or seriously deficient were withdrawn from sale; manufacturers relabeled such feeds correctly and made refunds to the agents and consumers.

Amendment of the State Feeding Stuffs Law.

Table 1—Calcium and phosphorus content of feeding stuffs.

Explanation of terms used in the analysis of feeds.

Table 2—Average analyses of the common cereals and by-product feeds.

Definitions of feeding stuffs.

Table 3—Summary of withdrawals of feed from sale.

Table 4—Estimated sales of various classes of feeding stuffs in 1933.

Table 5—Summary of the total annual tonnage and expenditures for commercial feeding stuffs since 1911.

Table 6—Summary of inspection giving the standing of each feed manufacturer.

COMMERCIAL FEEDING STUFFS

H. R. KRAYBILL, *State Chemist*

P. B. CURTIS, *Assistant Chemist* O. S. ROBERTS, *Chief Inspector*
Assistant Chemists, C. C. YUND, G. E. HALLIDAY, D. M. DOTY
Inspectors, C. M. COHEE, J. W. JACKMAN

The Indiana Feeding Stuffs Law is primarily a correct labeling law. It requires the manufacturer to state on the label minimum percentage guarantees for crude protein and crude fat, a maximum percentage guarantee for crude fiber and the specific name of each ingredient used in preparing the feed. Mineral feeds containing no organic ingredient do not require the usual chemical feed guarantee but do require a declaration of each ingredient contained therein and the minimum percentages of lime (CaO), phosphoric acid (P_2O_5), iodine (I) and the maximum percentage of salt (NaCl).

Amendment of Feeding Stuffs Law

The Indiana Feeding Stuffs Law as amended in 1933 permits the manufacturer or agent desiring to sell any concentrated commercial feeding stuff in packages of five pounds or less to register such feeding stuff under an annual registration fee of $20.00. If this method of registration is chosen it is not necessary for the manufacturer to attach Indiana state labels to the packages of feed of five pounds or less. However it is necessary for the manufacturer to print on his private label the following information: (1) The number of net pounds of concentrated commercial feeding stuff in the package; (2) the name, brand name or trade mark under which the concentrated commercial feeding stuff is sold; (3) the name of the manufacturer; (4) the location of the principal office of the manufacturer; (5) the guaranteed analysis stating the minimum percentages of crude protein and crude fat, the maximum percentage of crude fiber and the ingredients from which the concentrated commercial feeding stuff is compounded. This annual registration fee method applies only to feeding stuffs sold or offered for sale in packages of five pounds or less. Appropriate Official Indiana State Chemist tags or labels must be attached to all packages over five pounds. Copies of this amendment together with the law may be secured by making application to the State Chemist.

Results of Inspection

During the year 1933, 2,592 samples of commercial feeding stuffs were collected from manufacturers, dealers and consumers in the various sections of the state. One inspection sample was secured from approximately each 124 tons of commercial feed sold in Indiana. All of the 2,592 samples were examined microscopically and 2,311 of them were analyzed chemically for moisture, crude protein, crude fat, crude fiber and ash content. Fifty-two samples of mineral feed were analyzed for lime (CaO), phosphoric acid (P_2O_5), iodine (I) and salt (NaCl) content.

The results of inspection show that 82 per cent of the samples were equal to or better than the guarantee of the manufacturer as compared to 85 per cent in 1932. Of the 461 samples incorrectly guaranteed, 296 of them were classed as being seriously deficient or misbranded and not sold in accordance with the Indiana Feeding Stuffs Law.

Refunds

Shipments or batches of feed found to be seriously deficient were removed from sale immediately and the manufacturers were required to replace or rebuild such deficient lots to meet their guarantees or relabel them with correct guarantees. Refunds totaling $446.35 were made to dealers and consumers by 44 different feed manufacturers on 74 deficient lots of feed.

All refunds are required to be distributed to the consumer wherever possible and receipts for the same must be filed with the State Chemist. In case there are no records as to the consumer the refunds may be turned over to a local charitable organization but receipts for the same must be filed with the State Chemist.

The payment of a refund by the manufacturer to the consumer does not remove the violation but it does indicate good intentions on the part of the manufacturer and shows his willingness to do what he can to correct the violation. However, the payment of the refund does not nullify the right of anyone in the state to call a deficiency of analysis to the attention of the prosecuting attorney.

The most frequent violation of the Feeding Stuffs Law is in the matter of non-tagging (Table 3). Of the 554.8 tons of commercial feed withdrawn from sale 433.4 tons were removed because of the absence of Indiana State Chemist tags. While occasional unintentional errors may occur in tagging shipments of feed there is on the whole too much carelessness on the part of the manufacturer or distributor in attaching proper Indiana tags to their lots of feed sold or offered for sale in Indiana. Neglect on the part of the manufacturer, distributor or dealer may lead to serious violations of the Indiana Feeding Stuffs Law. On conviction, the penalty of such violations is fifty dollars for the first offense and one hundred dollars for each subsequent offense.

Estimated Sales of Commercial Feeding Stuffs in 1933

Computed from the sale of official state tags it is estimated that 322,318 tons of commercial feed with a retail value of $10,373,772 were sold in Indiana during the year 1933 (Table 4). From Table 5 it may be seen that the tonnage sold was approximately the same as was sold in each of the years 1931 and 1916. However, the retail value of the feed sold was slightly less than that of 1931. Compared with the sales of 1932 there was an increase of 31.5% in tonnage and a corresponding increase of 51% in expenditures. There were greater tonnages sold in practically all classes of feed but the principal increases in tonnage were for hominy feed, mill by-products, poultry mash and proprietary feeds.

Attention Manufacturers, Dealers and Consumers

The Official State Tag required by the Indiana Feed Law bears the facsimile signature of the State Chemist and states the manufacturer's guarantee. Manufacturers and dealers should not neglect to attach these Official Indiana Tags to each and every bag of feed sold or offered for sale in Indiana. Furthermore, the Official Tag must not be mutilated or altered in any way whatsoever.

Dealers and consumers should become acquainted with the definitions and terms used in the analysis of feeding stuffs. This information is included in this circular. Table 6 entitled "The Summary of Feed Inspection" may also be of value to the purchasers of commercial feeds.

If information regarding formulas is desired, the various Departments of the Purdue University Agricultural Experiment Station should be consulted. After certain feed formulas have been devised or selected, Table 2, entitled "Average Analyses of Cereals and By-Products," may be helpful to those who wish to calculate safe guarantees for their formulas.

Manufacturers of mineral feeds having difficulty in computing minimum percentage guarantees of lime (CaO) and phosphoric acid (P_2O_5) for their products should refer to Table 1, entitled "Calcium and Phosphorus Content of Feeding Stuffs." Poultrymen and others interested in maintaining a definite calcium and phosphorus ratio in their feeds will also find valuable information in this table. Since minimum percentages of lime expressed as (CaO) and phosphoric acid expressed as (P_2O_5) are required in the guarantee of mineral feeds these values are stated rather than the actual percentages of calcium and phosphorus. If the percentage of calcium is desired the percentage of lime (CaO) must be multiplied by 0.7. If the percentage of phosphorus is desired the percentage of phosphoric acid (P_2O_5) must be multiplied by 0.44.

Table 1.—Calcium and Phosphorus Content of Feeding Stuffs

Material	Lime (CaO) %	Phosphoric Acid (P_2O_5) %
Alfalfa meal	1.70	0.53
Brewers' dried grains	0.22	1.03
Buttermilk dried	3.40	2.20
Corn	0.02	0.65
Corn gluten feed	0.35	0.62
Cottonseed meal	0.37	2.89
Cowpeas	0.14	1.02
Distillers' grain corn	0.06	0.67
Fish meal (20.0% ash)	9.30	8.00
Hominy feed	0.04	1.03
Linseed oil meal	0.51	1.65
Malt sprouts	0.21	1.61
Meat and bone scraps (30.0% ash)	15.14	11.21
Oats	0.14	0.85
Skimmed milk dried	1.80	2.20
Soy beans	0.29	1.37
Soy bean oil meal	0.38	1.75
Tankage digester (20.0% ash)	9.00	7.25
Wheat	0.06	0.86
Wheat bran	0.13	2.74
Wheat middlings	0.10	2.06
Wheat red dog flour	0.17	1.95
Bone meal steamed	40.00	30.00
Bone black	40.00	30.00
Dicalcium phosphate	32.00	40.00
Rock phosphate	40.00	30.00
Super phosphate 16%	24.00	16.00
Super phosphate 20%	25.00	20.00
Phosphatic limestone	50.00	10.00
Limestone (95% calcium carbonate)	53.00	
Oyster shells (95% calcium carbonate)	53.00	
Wood ashes	30.00	
Gypsum	35.00	

Explanation of Terms Used in the Analysis of Feeding Stuffs

Moisture is the varying quantity of water occurring in feeding stuffs which can be driven off by heat at the temperature of boiling water. The amount of water present varies with the temperature, moisture content of the air, processes of manufacture and the character of the substance. In most concentrates this value ranges from 5 to 15 per cent.

Crude Fat consists mainly of fats and oils with small amounts of waxes, resins, coloring matter and similar substances, dissolved from feeding stuffs by dry ether. In calculating the heat and energy value of a feed, the fat is considered 2.25 times greater than that of either carbohydrates or protein.

Crude Protein is the term applied to the nitrogenous constituents of a feeding stuff. It is obtained by multiplying the total nitrogen by 6.25. Protein is the most important as well as the most costly constituent in a feed. Plants have the power of building up protein from the inorganic elements of the soil and air while animals must secure their protein from the plants or other animals. The plant proteins contain varying amounts of the essential amino acids, therefore it is necessary to carefully select a variety of feeds which will furnish the essential amino acids economically.

Crude Fiber is the woody portion of a feeding stuff, for the most part cellulose, and is insoluble in dilute acids and alkalis. Most of the common seeds and grains contain very little fiber while the hulls, husks and stems are high in this constituent. In poultry and swine, crude fiber when present in considerable quantities exerts a retarding influence on the digestion of nutrients present.

Ash, the mineral matter of plants, is the residue left after burning a feeding stuff at low redness. It consists chiefly of the phosphates, sulphates, chlorides and carbonates of sodium, potassium, calcium and magnesium. The calcium and phosphorus are absolutely essential for the proper nutrition of the animal.

Nitrogen Free Extract consists of sugars, starches, pentoses, non-nitrogenous organic acids, etc., and is determined by subtracting the sum of moisture, crude fat, crude protein, crude fiber and ash from 100.

Carbohydrates is the sum of the crude fiber and nitrogen-free extract.

Table 2.—Average Analysis of Cereals and By-Products

Material	Description of	Pounds in One Hundred		
		Crude Fat	Crude Protein	Crude Fiber
Alfalfa meal	Entire ground hay	1.5	13.0	33.0
Alfalfa leaf meal	Largely alfalfa leaves	2.5	20.0	18.0
Barley	Whole or ground	1.8	11.0	6.0
Beet pulp	Dried	0.9	8.5	18.0
Blood (dried)	Blood meal	0.5	80.0	none
Bone (raw)	Raw bone	3.0	20.0	1.0
Bone (steamed)	Steamed bone	0.5	6.0	1.0
Brewers' dried grains	From manufacture of beer	6.0	26.0	15.0
Buckwheat	Whole or ground	2.2	10.0	10.0
Buckwheat mixed feed	Entire product from manufacture of buckwheat flour	3.2	12.0	28.0
Buckwheat middlings	Entire product from manufacture of buckwheat flour, except the hulls	7.3	28.8	6.4
Buttermilk (dried)	Dried buttermilk	5.0	30.0	none
Buttermilk (condensed)	Condensed buttermilk	2.0	10.0	none
Cane seed	(Sorghum) removed from head and cleaned	2.5	9.0	2.5
Charcoal	Charcoal	none	none	90.0
Cob meal	Ground corn cob	0.5	2.0	31.0
Cocoanut oil meal	Dried cocoanut meats with partial extraction of oil	8.0	22.0	9.0
Corn	Old corn No. 2	4.0	9.5	2.0
Corn and cob meal	Ear corn (old)	3.5	8.0	8.0
Corn bran	Containing little corn germ	2.5	7.0	10.0
Corn mill feed	Corn bran germ and some meal from manufacture of meal or corn flour	7.4	11.0	4.2
Corn feed meal	Manufacture of cracked corn	3.5	9.0	2.0
Corn germ oil meal	Corn germ with part of the oil removed	8.0	20.0	8.0
Corn gluten feed	Remains after the larger part of starch and germ is removed	2.0	25.0	7.0
Corn gluten meal	From manufacture of corn starch and glucose	1.0	42.0	2.0
Corn screenings	Small and broken grains of corn, small pieces cob, etc., removed from shelled corn	2.7	8.6	8.6
Cottonseed meal (prime quality)	Sold as 36 per cent protein	6.0	36.0	14.0
Cottonseed meal (prime quality)	Sold as 41 per cent protein	6.0	41.0	12.0
Cottonseed meal (prime quality)	Sold as 43 per cent protein	6.0	43.0	10.0
Cottonseed feed	Below 36 per cent protein	4.0	22.8	22.0
Cottonseed hulls	Contains trace of lint and meal adhering	1.8	4.6	38.0
Cowpea	Seeds, pods removed	1.4	20.8	4.1
Distillers' grain (dried)	From corn or rye	9.0	27.0	12.0
Emmer	Often called spelt	2.0	11.5	10.0
Fish meal	Dried ground tissues of fish with or without the extraction of part of the oil	6.0	55.0	2.0
Flaxseed	Whole grain or meal without extraction of oil	32.0	22.0	7.0
Flax plant by-product	Shives, pods, etc.	2.1	15.0	31.0
Flaxseed screenings	Small and broken grains, flaxseed, weed seed and other foreign material cleaned from flaxseed	8.0	14.0	14.0
Hominy feed, meal or chop	Manufacture of hominy grits or meal by degerminator process	6.0	11.0	6.0
Kaffir corn	Milo	2.5	10.0	2.5
Kelp (dried)	Ground dried kelp	1.0	6.0	10.0
Linseed meal (old process)	Oil extracted by pressure	6.0	34.0	8.0
Malt sprouts	Sprout of the barley grain	1.3	27.9	12.1

Meat scraps or meat and bone scraps	Ground dry rendered residue from animal tissues	6.0	50.0	3.0
Millet	Italian millet seed	3.9	10.3	9.4
Milo	Whole or ground	2.5	10.7	2.5
Molasses	From beets	none	3.0	....
Molasses	Blackstrap from cane	none	3.0	....
Oats	Ground or whole	4.0	11.0	11.0
Oat-clipped by-product	Clippings	2.0	9.0	30.0
Oat-groats	Kernels of oat berry	6.5	15.0	2.0
Oat hulls	Oat hulls	1.5	4.0	32.0
Oat meal mill by-product	Oat hulls and oat shorts	1.5	6.0	28.0
Oat middlings	Floury portion of oat groat	5.0	15.0	5.0
Peanut oil feed	Peanut meats and peanut hulls	6.0	30.0	25.0
Peanut oil meal	Residue after the extraction of part of the oil from peanut kernels	6.0	40.0	6.0
Peanut shells	Whole or finely ground	1.2	5.5	70.9
Rice bran	Cuticle layer beneath hull	12.0	12.0	12.0
Rye	Rye	1.5	11.0	2.0
Rye feed	Rye feed	3.5	16.0	5.0
Skimmed milk (dried)	Dried skimmed milk	0.5	30.0	none
Soybean	Seed pods removed	19.0	35.0	5.0
Soybean oil meal	Ground	6.0	40.0	6.0
Sunflower seed	Whole or ground	19.0	16.0	30.0
Tankage (digester)	60 per cent reinforced with concentrated tank water or dried blood	6.0	60.0	3.0
Unscreened flaxseed oil feed	Flaxseed meal and flaxseed screenings	6.0	30.0	9.0
Velvet bean feed	Velvet beans and pods	4.0	19.0	17.0
Wheat	Whole or ground	1.9	11.9	2.4
Wheat bran (soft)	Wheat bran	3.5	14.5	8.0
Wheat bran (hard)	Wheat bran	4.0	16.0	10.0
Wheat middlings	Wheat middlings	3.5	15.5	6.0
Wheat standard middlings	With and without screenings	4.0	16.0	9.5
Wheat red dog flour	Red dog flour	3.5	15.0	4.0
Wheat mixed feed and mill run screenings	Bran, middlings, red dog flour and screenings	3.5	15.0	8.0
Whey (dried)	Dried whey	0.5	12.0	none

DEFINITIONS OF FEEDING STUFFS*

Alfalfa Products

1. **Chopped Alfalfa** is the entire alfalfa hay, chopped and not ground finely enough to become a meal. It must not contain an admixture of alfalfa straw or other foreign material. (Adopted prior to 1928.)

2. **Alfalfa Meal** is the product obtained from the grinding of the entire alfalfa hay, without the addition of any alfalfa stems, alfalfa straw or foreign material, or the abstraction of leaves. It must be reasonably free from other crop plants and weeds, and must not contain more than 33 per cent of crude fiber. (Adopted 1928.)

3. **Alfalfa Leaf Meal** is the ground product consisting chiefly of leafy materials separated from alfalfa hay. It must be reasonably free from other crop plants and weeds and must not contain more than 18 per cent of crude fiber. (Adopted 1928.)

4. **Alfalfa Stem Meal** is the ground product remaining after the separation of the leafy material from alfalfa hay or meal. It must be reasonably free from other crop plants and weeds. (Adopted 1928.)

Animal Products

5. **Blood Meal** is ground, dried blood. (Adopted 1926.)

6. **Blood Flour** is dried blood, prepared by special processes and reduced to a fine powder. (Adopted prior to 1928.)

7. **Digester Tankage, Meat Meal Tankage or Feeding Tankage** is the residue from animal tissues exclusive of hoof, horn, manure and stomach contents, except in such traces as might occur unavoidably in good factory practice, especially prepared for feeding purposes by tanking under live steam or by dry rendering or a mixture of the products made suitable by drying and grinding. It must not contain more than 10% of phosphoric acid (expressed as P_2O_5). If it bears a name descriptive of its kind, composition or origin, the material must correspond thereto. (Adopted 1928—Amended 1933.)

8. **Digester Tankage with Bone, Meat and Bone Meal Digester Tankage, Meat and Bone Meal Tankage, or Feeding Tankage with Bone** is the residue from animal tissues exclusive of hoof, horn, manure and stomach contents, except in such traces as might occur unavoidably in good factory practice, especially prepared for feeding purposes by tanking under live steam or by dry rendering or a mixture of the products made suitable by drying and grinding, and containing more than 10% of phosphoric acid (expressed as P_2O_5). If it bears a name descriptive of its kind, composition or origin, it must correspond thereto. (Adopted 1928—Amended 1933.)

9. **Meat Scraps** is the ground, dry-rendered residue from animal tissues exclusive of hoof, horn, manure and stomach contents, except in such traces as might occur unavoidably in good factory practice. When this product contains more than 10% of phosphoric acid (expressed as P_2O_5), it shall be desig-

---

* These definitions have been adopted by the Association of American Feed Control Officials.

nated Meat and Bone Scrap. If it bears a name descriptive of its kind, composition or origin it must correspond thereto. (Adopted 1928.)

10. **Raw Bone Meal** is the dried, ground product suitable for animal feeding, obtained by cooking in water at atmospheric pressure, undecomposed bone, just enough to remove excess fat and meat. It must not contain less than 23 per cent of protein. (Adopted 1929.)

11. **Steamed Bone Meal** is the dried, ground product suitable for animal feeding obtained by cooking bones with steam under pressure. (Adopted 1929.)

12. **Special Steamed Bone Meal** is the dried, ground product suitable for animal feeding obtained by cooking dried bone after the removal of grease and meat fiber with steam under pressure in the process of obtaining gelatine or glue. (Adopted 1929.)

Apple Products

13. **Dried Apple Pomace** is the sound, dried residue obtained by the removal of cider from apples. (Adopted 1929.)

14. **Dried Apple Pectin Pulp** is the sound, dried residue obtained by the removal of pectin from apple products. (Adopted 1929.)

Barley Products

15. **Barley Hulls** is the product consisting of the outer coverings of the barley. (Adopted prior to 1928.)

16. **Barley Feed** is the entire by-product resulting from the manufacture of pearl barley from clean barley. (Adopted prior to 1928.)

17. **Barley Mixed Feed** is the entire offal from the milling of barley flour from clean barley and is composed of barley hulls and barley middlings. (Adopted prior to 1928.)

18. **Ground Barley** is the entire product obtained by grinding clean sound barley, containing not less than 90 per cent of pure barley and not more than 10 per cent of other grains, weed seeds and other foreign material and not more than 6 per cent of crude fiber; provided that no portion of this stated 10 per cent of other grains, weed seeds or other foreign material shall be intentionally added. (Adopted prior to 1928.)

19. **Mixed Feed Barley** is the entire product obtained by grinding country run barley containing not less than 75 per cent of pure barley and not more than 25 per cent of other grains, weed seeds and other foreign material; provided that no portion of this stated 25 per cent of other grains, weed seeds or foreign material shall be intentionally added. The ingredients must be stated as barley, other grains, weed seeds and foreign material. (Adopted prior to 1928.)

Beet Products

20. **Dried Beet Pulp** is the dried residue from sugar beets which have been cleaned and freed from crowns, leaves and sand, and from which the sugar has been extracted. (Adopted prior to 1928.)

Brewers' and Distillers' Products

21. **Brewers' Dried Grains** is the dried residue obtained in the manufacture of beer. (Adopted prior to 1928.)

22. **Distillers' Corn Dried Grain or Distillers' Rye Dried Grains** is the dried residue obtained in the manufacture of alcohol and distilled liquors. The product must bear the designation indicating the cereal predominating. (Adopted prior to 1928.)

23. **Distillers' Corn Solubles** is a by-product from the manufacture of alcohol from corn solids obtained by the evaporation of the mash liquor after the removal of the alcohol and wet grains. (Adopted prior to 1928.)

24. **Distillers' Rye Solubles** is a by-product from the manufacture of alcohol from rye solids obtained by the evaporation of mash liquor after the removal of the alcohol and wet grains. (Adopted prior to 1928.)

25. **Distillers' Corn and Rye Solubles** is a by-product from the manufacture of alcohol from corn and rye solids obtained by the evaporation of mash liquor after the removal of the alcohol and wet grains. (Adopted prior to 1928.)

26. **Malt Sprouts** are the sprouts of the barley grain obtained from malted barley. Sprouts derived from any other malted cereal must be designated by the name of that cereal. (Adopted prior to 1928.)

27. **Yeast Dried Grains or Vinegar Dried Grains** is the properly dried residue from the mixture of cereals, malt and malt sprouts (sometimes cottonseed meal) obtained in the manufacture of yeast or vinegar, and consists of corn or corn and rye from which most of the starch has been extracted together with malt added during the manufacturing process to change the starch to sugars, and malt sprouts (sometimes cottonseed meal) added during the manufacturing process to aid in filtering the residue from the wort and to serve as a source of food supply for the yeast. (Adopted prior to 1928.)

Buckwheat Products

28. **Buckwheat Shorts or Buckwheat Middlings** are the portions of the buckwheat grain immediately inside the hull secured after separation from the flour. (Adopted prior to 1928.)

Chop

29. **Chop** is a ground or chopped feed composed of one or more different cereals or by-products thereof. If it bears a name descriptive of the kind of cereals, it must be made exclusively of the entire grains of those cereals (Adopted prior to 1928.)

Cocoanut Products

30. ....**Per Cent Protein Cocoanut Oil Meal or....Per Cent Protein Copra Oil Meal** is the ground residue from the extraction of part of the oil from the dried meat of the cocoanut. (Adopted prior to 1928.)

Corn Products

31. **Corn Meal** (Feeding) is finely ground, unbolted corn. (Adopted prior to 1928.)

32. **Corn Bran** is the outer coating of the corn kernel, with little or none of the starchy part or germ. (Adopted 1931.)

33. **Corn Feed Meal** is the fine siftings obtained in the manufacture o screened corn chop, screened ground corn or screened cracked corn, with o without its aspiration products added. (Adopted 1931.)

34. **Corn Chop, Ground Corn or Cracked Corn** is the entire product mad by grinding, cutting or chopping the grains of sound Indian corn, and may b fine, medium or coarse, and must not contain more than 4 per cent of foreign material. (Adopted 1931.)

35. **Screened Corn Chop, Screened Ground Corn, or Screened Cracke Corn** is the coarse portion of corn chop, ground corn or cracked corn from which most of the fine particles have been removed, and must not contain more than 4 per cent of foreign material. (Adopted 1931.)

36. **Corn Grits or Hominy Grits** is the product consisting of the fine o medium sized, hard flinty portions of sound Indian corn containing little o none of the bran or germ. (Adopted 1931.)

37. **Ear Corn Chops** is corn and cob chopped, without the husk, with n greater proportion of cob than occurs in the ear corn in its natural state (Adopted prior to 1928.)

38. **Corn Gluten Meal** is that part of commercial shelled corn that remain after the separation of the larger part of the starch, the germ and the bran by the processes employed in the manufacture of corn starch. It may or ma not contain corn solubles. (Adopted prior to 1928.)

39. **Corn Gluten Feed** is that part of commercial shelled corn that remain after the separation of the larger part of the starch and the germs by th processes employed in the manufacture of corn starch. It may or may no contain corn solubles. (Adopted prior to 1928.)

40. **Maltose Process Corn Gluten Feed** is the dried residue from degerme corn, after removal of starch in the manufacture of malt syrup. (Adopte prior to 1928.)

41. **Hominy Feed, Hominy Meal or Hominy Chop** is the kiln-dried mixtur of the mill-run bran coating, the mill-run germ, with or without a partial extraction of the oil, and a part of the starchy portion of the white corn kernel obtained in the manufacture of hominy, hominy grits, and cornmeal by the degerming process. (Adopted prior to 1928.)

42. **Yellow Hominy Feed, Yellow Hominy Meal or Yellow Hominy Chop** is the kiln-dried mixture of the mill-run bran coating, the mill-run germ, with or without a partial extraction of the oil, and a part of the starchy portion of the yellow corn kernel obtained in the manufacture of yellow hominy grits and yellow corn meal by the degerming process. (Adopted prior to 1928.)

43. **Corn Oil Cake** consists of the corn germ from which part of the oil has been pressed and is the product obtained in the wet milling process of manufacture of corn starch, corn syrup, and other corn products. (Adopted prior to 1928.)

44. **Corn Oil Meal** is ground corn oil cake. (Adopted prior to 1928.)

45. **Corn Germ Cake** consists of corn germ with other parts of the corn kernel from which part of the oil has been pressed, and is the product obtained in the dry milling process of manufacture of corn meal, corn grits, hominy feed, and other corn products. (Adopted prior to 1928.)

46. **Corn Germ Meal** is ground corn germ cake. (Adopted prior to 1928.)

47. **Corn Screenings** is the product consisting of the small light grains of corn, part of grains of corn and/or other cereals, and other materials having feed value, obtained by screening shelled corn, excluding sand, dirt and other similar inert materials. (Adopted 1931.)

Cottonseed Products

48. **Cottonseed Meal** is a product of the cottonseed only, composed principally of the kernel with such portion of the hull as is necessary in the manufacture of oil; provided that nothing shall be recognized as cottonseed meal that does not conform to the foregoing definition and that does not contain at least 36 per cent of protein. Cottonseed meal shall be graded and classed as follows: (Adopted prior to 1928.)

49.....**Per Cent Protein Cottonseed Meal, Prime Quality.** Cottonseed meal, prime quality, must be finely ground, not necessarily bolted, of sweet odor, reasonably bright in color, yellowish, not brown or reddish, free from excessive lint, and shall contain not less than 36 per cent of protein. It must be designated and sold according to its protein content. Cottonseed meal with 36 per cent of protein must be termed "36 per cent Protein Cottonseed Meal, Prime Quality," and higher grades similarly designated (as "43 per cent Protein Cottonseed Meal, Prime Quality"), etc. (Adopted prior to 1928.)

50.....**Per Cent Protein Cottonseed Meal, Off Quality.** Cottonseed meal not fulfilling the above requirement as to color, odor and texture must be graded "36 per cent Protein Cottonseed Meal, Off Quality," and higher grades similarly designated. (Adopted prior to 1928.)

51. **Cottonseed Feed** is a mixture of cottonseed meal and cottonseed hulls, containing less than 36 per cent of protein. (Adopted prior to 1928.)

52.....**Per Cent Protein Whole Pressed Cottonseed,** Prime Quality, is the product resulting from subjecting the whole, sound, mature, clean undecorticated cottonseed to pressure for the extraction of oil, and includes the entire cottonseed less the oil extracted and the lint removed. It must be designated and sold according to its protein content. (Adopted 1932.)

53.....**Per Cent Protein Ground Whole Pressed Cottonseed,** Prime Quality, is whole pressed cottonseed, ground. It must be designated and sold according to its protein content. (Adopted 1932.)

Garbage

54. **Processed Garbage** is composed of dried animal and vegetable waste from garbage collected sufficiently often that harmful decomposition has not set in, and separated from material such as crockery and glass. Its odor must not be suggestive of the presence of decomposition and it must contain less than one per cent of glass. None of it shall contain knife-like or needle-like particles, and the maximum percentage of glass should be stated on the label when present in excess of one-fifth of one per cent. (Adopted prior to 1928.)

Ivory Nut Products

55. **Ivory Nut Meal** is the ground waste material resulting from the manufacture of buttons and similar articles from the vegetable ivory nut. (Adopted prior to 1928.)

Linseed and Flax Products

56.....**Per Cent Protein Linseed Cake or Linseed Meal** is the product obtained in the removal of the oil from flaxseed; provided that the final product contains less than 6 per cent of weed seeds and other foreign materials; and provided, further, that no portion of the stated 6 per cent of weed seeds and other foreign materials shall be deliberately added. It shall not contain more than 0.5 per cent of acid insoluble ash. (Adopted 1933.)

57.....**Per Cent Protein Old Process Oil Meal or....Per Cent Protein Old Process Linseed Meal** is oil meal as defined below, produced by crushing, cooking and hydraulic pressure. (Adopted prior to 1928.)

58.....**Per Cent Protein New Process Oil Meal or....Per Cent Protein New Process Linseed Meal** is oil meal as defined below, produced by crushing, heating and the use of solvents. (Adopted prior to 1928.)

59. **Flax Plant By-Product** is that portion of the flax plant remaining after the separation of the seed, the bast fiber and a portion of the shives, and consists of flax shives, flax pods, broken and immature flax seeds, and the cortical tissues of the stem. (Adopted prior to 1928.)

60. **Ground Flaxseed or Flaxseed Meal** is the product obtained by grinding flaxseed which has been screened and cleaned of weed seeds and other foreign materials by the most improved commercial process; the final product must contain less than 4 per cent of weed seeds and other foreign materials, and no portion of the stated 4 per cent of weed seeds and other foreign materials shall be intentionally added. (Adopted prior to 1928.)

61. **Unscreened Flaxseed Oil Feed Cake** is the product obtained by extraction of part of the oil from unscreened flaxseed by crushing, cooking and hydraulic pressure, or by crushing, heating and the use of solvents. The ingredients must be stated as "partially extracted flaxseed and foreign seeds (wheat, wild buckwheat, pigeon grass, wild mustard, etc.)." (Adopted prior to 1928.)

62. **Ground Unscreened Flaxseed Oil Feed** is the ground unscreened flaxseed oil feed cake. (Adopted prior to 1928.)

63. **Screenings Oil Feed** is the ground product obtained after extraction of part of the oil by crushing, cooking and hydraulic pressure, or by crushing, heating and the use of solvents from the smaller imperfect flaxseed, weed seeds and other foreign materials having feeding value, separated in cleaning flaxseed. The name of the grain from which the screenings are separated must be prefixed to "screenings oil feed." (Adopted prior to 1928.)

64.....**Per Cent Protein Oil Cake** is the product obtained after the extraction of part of the oil by crushing, cooking, and hydraulic pressure, or by crushing, heating and the use of solvents, from flaxseed which have been screened and cleaned of weed seeds and other foreign materials by the most improved commercial process. When used alone the term "Oil Cake" shall be understood to designate linseed cake as defined. When used to cover any other products the name of the seed from which it is obtained must be prefixed to the words "Oil Cake." (Adopted prior to 1928.)

65.....**Per Cent Protein Oil Meal or .... Per Cent Protein Ground Oil Cake** is oil cake ground to a meal. (Adopted prior to 1928.)

Marine Products

66. **Fish Meal** (Feeding) is clean, dried, ground tissues of undecomposed whole fish and/or fish cuttings with or without the extraction of part of the oil, and contains not more than 3 per cent of salt (NaCl). If it contains more than 3 per cent of salt (NaCl) the amount of salt must constitute a part of the brand name, provided that in no case shall the salt content of this product exceed 7 per cent. (Adopted 1933.)

67. **Fish Residue Meal** (Feeding) is the clean, dried, undecomposed residue from the manufacture of glue from non-oily fish, and contains not more than 3 per cent of salt (NaCl). If it contains more than 3 per cent of salt (NaCl) the amount of salt must constitute a part of the brand name, provided that in no case shall the salt content of this product exceed 7 per cent. (Adopted 1933.)

68. **Crab Meal** (Feeding) is prepared from the undecomposed dried waste of the crab industry and contains the shell, viscera and part or all of the flesh. It contains not less than 25 per cent of protein and not more than 3 per cent of

salt (NaCl). If it contains more than 3 per cent of salt (NaCl) the amount of salt must constitute a part of the brand name, provided that in no case shall the salt content of this product exceed 7 per cent. (Adopted 1933.)

69. **Shrimp Meal** (Feeding) is prepared from the undecomposed dried waste of the shrimp industry and contains the heads, hull and/or the whole shrimp and not more than 3 per cent of salt (NaCl). If it contains more than 3 per cent of salt (NaCl) the amount of salt must constitute a part of the brand name, provided that in no case shall the salt content of this product exceed 7 per cent. (Adopted 1933.)

70. **Whale Meal** (Feeding) is prepared from the clean, dried undecomposed flesh of the whale, after part of the oil has been extracted. It contains not more than 3 per cent of salt (NaCl). If it contains more than 3 per cent of salt (NaCl) the amount of salt must constitute a part of the brand name, provided that in no case shall the salt content of this product exceed 7 per cent. (Adopted 1933.)

71. **Cod Liver Oil** is the product obtained by extraction of part of the oil from cod livers. (Adopted 1932.)

72. **Sardine Oil or Pilchard Oil** is the product obtained by extraction of part of the oil from the whole Pacific sardine or pilchard or from cannery refuse of this species of fish. (Adopted 1932.)

73. **Salmon Oil** is the product obtained by extraction of part of the oil from the cannery refuse of salmon. (Adopted 1932.)

74. **Tuna Oil** is the product obtained by extraction of part of the oil from the cannery refuse of tuna. (Adopted 1932.)

75. **Menhaden Oil** is the product obtained by extraction of part of the oil from whole Menhaden. (Adopted 1932.)

76. **Herring Oil** is the product obtained by extraction of part of the oil from the whole herring or part of the herring. (Adopted 1933.)

77. **Salmon Liver Oil** is the product obtained by extraction of part of the oil from salmon livers. (Adopted 1933.)

Milk Products

78. **Dried Buttermilk** (Feeding) is the product resulting from the removal of water from clean, sound buttermilk derived from natural cream to which no foreign substances have been added, excepting such as are necessary and permitted in the manufacture of butter. It contains not more than 8 per cent of moisture, not more than 13 per cent of mineral matter (ash), and not less than 5 per cent of butterfat, as determined by the Roese-Gottlieb method. (Adopted 1932.)

79. **Evaporated Buttermilk** (Feeding), **Concentrated Buttermilk** (Feeding) or **Condensed Buttermilk** (Feeding) is the product resulting from the removal of a considerable portion of water from clean, sound buttermilk derived from natural cream to which no foreign substances have been added excepting such as are permitted and necessary in the manufacture of butter. It contains not less than 27 per cent of total solids, not less than 2 per cent of butterfat, and not more than .14 per cent of ash for each per cent of solids. This definition does not prohibit the use of a distinctive trade name, provided it is followed by one of the names given. (Adopted prior to 1928.)

80. **Dried Skimmed Milk** (Feeding) is the product resulting from the removal of water from clean, sound skimmed milk. It contains not more than 8 per cent of moisture. (Adopted 1930.)

81. **Dried Soured Skimmed Milk** (Feeding) is the product resulting from the removal of water from clean, sound skimmed milk which has been soured by a suitable culture of lactic bacteria. It contains not more than 8 per cent of moisture. (Adopted 1932.)

82. **Evaporated Soured Skimmed Milk** (Feeding), **Concentrated Soured Skimmed Milk** (Feeding) or **Condensed Soured Skimmed Milk** (Feeding) is the product resulting from the removal of a considerable portion of water from clean, sound skimmed milk which has been soured by a suitable culture of lactic bacteria. It contains not less than 27 per cent of total solids. (Adopted 1932.)

83. **Condensed Skimmed Milk** (Feeding) is the product resulting from the removal of a considerable portion of water from clean, sound skimmed milk. It contains not less than 27 per cent of total solids. (Adopted 1930.)

84. **Milk Sugar Feed or Dried Whey** (Feeding) is the by-product from the manufacture of cheese and should contain at least 70 per cent of lactose (milk sugar). (Adopted 1932.)

Mineral Feeds

85. Mixed feeds containing both feed and more than 5 per cent of mineral ingredients requires, in addition to the usual declaration of the chemical feed analysis, a declaration of each ingredient contained therein and the minimum percentages of lime expressed as CaO, phosphoric acid expressed as P_2O_5, iodine (I), and the maximum percentage of salt (NaCl) if same be present. If minerals predominate in the mixture, the usual declaration of the chemical feed analysis, with the exception of protein, may be omitted.

In mineral feeds containing no organic ingredient, the usual chemical feed guarantee need not be made. A declaration should be made of each ingredient contained therein and the minimum percentage of lime expressed as CaO, phosphoric acid expressed as P_2O_5, iodine (I), and the maximum percentage of salt (NaCl) if same be present.

The mineral ingredients should be stated in the common English terms, if any such terms exist.

It being impossible to classify separately the drug ingredients and the mineral ingredients, be it resolved:

(a) That all mixtures containing mineral ingredients generally regarded as dietary factors essential for the normal nutrition of animals and which are sold or represented for the primary purpose of supplying these minerals as additions to rations in which these same mineral factors may be deficient, be classified as mineral feeds.

(b) That all other preparations which are sold or represented primarily for the cure, mitigation or prevention of disease be classified by this Association as drugs, medicines or specifics. (Adopted prior to 1928.)

Oat Products

86. **Oat Hulls** is the product consisting of the outer covering of the oat. (Adopted prior to 1928.)

87. **Oat Middlings** is the product consisting of the floury portions of the oat groat obtained in the milling of rolled oats . (Adopted prior to 1928.)

88. **Oat Shorts** is the product consisting of the covering of the oat grain lying immediately inside the hull, being a fuzzy material carrying with it considerable portions of the fine floury part of the groat obtained in the milling of rolled oats. (Adopted prior to 1928.)

89. **Oat Chop, Ground Oats, Pulverized Oats, Crushed Oats, or Crimped Oats** consists of the entire product made by chopping, cutting, grinding, crushing, or crimping whole oats. (Adopted 1931.)

90. **Oat Groats** are the kernels produced from cleaned and dried oats in the process of manufacturing oat meal. (Adopted 1931.)

91. **Hulled Oats, or Undried Oat Groats** are the kernels produced from the undried grain in the process of hulling oats. (Adopted 1931.)

92. **Oat Meal, or Ground Oat Groats** is the product produced by cutting, cracking or grinding oat groats. (Adopted 1931.)

93. **Rolled Oat Groats or Rolled Oats** is the product obtained in the process of rolling oat groats. (Adopted 1931.)

94. **Clipped Oat By-Products** is the by-product obtained in the manufacture of clipped oats. It may contain the light chaffy material broken from the end of the hulls, empty hulls, light immature oats and dust. It must not contain an excessive amount of oat hulls. (Adopted prior to 1928.)

95. **Oat Mill Feed** (Oat Hulls, Oat Shorts and Oat Middlings) is the entire by-product produced in the manufacture of oat groats and consists of oat hulls, oat shorts and oat middlings. If used in a mixed feed, it shall be called Oat Mill Feed (oat hulls, oat shorts and oat middlings). (Adopted 1932.)

Palm Products

96. **Palm Kernel Oil Meal** is the ground residue from the extraction of part of the oil by pressure or solvents from the kernel of the fruit of Elaeis guineensis or Elaeis molanococco. (Adopted prior to 1928.)

Peanut Products

97.....**Per Cent Protein Peanut Oil Cake** is the residue after the extraction of part of the oil by pressure or solvents from peanut kernels. (Adopted prior to 1928.)

98.....**Per Cent Protein Peanut Oil Meal** is ground peanut oil cake. (Adopted prior to 1928.)

99. **Unhulled Peanut Oil Feed** is the ground residue obtained after extraction of part of the oil from whole peanuts, and the ingredients must be designated as **Peanut Meal and Hulls.** (Adopted prior to 1928.)

Rice Products

100. **Rice Bran** is the pericarp or bran layer of the rice, with only such quantity of hull fragments as is unavoidable in the regular milling of rice. (Adopted prior to 1928.)

101. **Rice Hulls** is the product consisting of the outer coverings of the rice. (Adopted prior to 1928.)

102. **Rice Polish** is the finely powdered material obtained in polishing the kernel. (Adopted prior to 1928.)

103. **Rice Meal** is ground brown rice or ground rice after the hull has been removed. (Adopted prior to 1928.)

104. **Ground Rough Rice** is ground rice from which the hull has not been removed or ground paddy rice. (Adopted prior to 1928.)

105. **Rice Stone Bran** is the siftings from the materials secured in removing hulls from rice and contains rice germs, broken rice and some rice hulls. (Adopted prior to 1928.)

106. **Rice Huller Bran** is a product secured by the huller and cones from brown rice and consists mostly of the bran and germs. (Adopted prior to 1928.)

Rye Products

107. **Rye Bran** is the coarse outer covering of the rye kernel as separated from the cleaned and scoured rye. (Adopted prior to 1928.)

108. **Rye Feed** is a by-product obtained in the usual process of the milling of rye flour from cleaned and scoured rye grain, consisting principally of the mill-run of the outer covering of the rye grain and the germ with small quantities of flour and aleurone. (Adopted prior to 1928.)

109. **Rye Red Dog** is a by-product obtained in the usual process of the milling of rye flour, consisting principally of aleurone with small quantities of flour and fine bran particles and must not contain more than 3.5 per cent of crude fiber. (Adopted prior to 1928.)

110. **Rye Low-Grade Feed Flour** consists principally of dark rye flour and small quantities of aleurone and fine bran particles and must not contain more than 1.5 per cent of crude fiber. (Adopted prior to 1928.)

111. **Rye Middlings** consists of rye feed and rye red dog combined in the proportions obtained in the usual process of milling rye flour. (Adopted prior to 1928.)

112. **Rye Flour Middlings** consist of rye feed, rye red dog and pure dark rye flour combined in the proportions obtained in the milling of rye flour and must not contain more than 5 per cent of crude fiber. (Adopted prior to 1928.)

Sorghum Products

113. **Head Chops** is the product consisting of the entire heads of the grain sorghums chopped, and should bear the name of the sorghum from which it is made. This includes, among others, kaffir head chops, milo head chops, feterita head chops, and sorghum head chops. (Adopted prior to 1928.)

114. **Head Stems** is the product consisting of the stems from the heads of the grain sorghums after the grain has been removed, and should bear the name of the sorghum from which it is made. (Adopted prior to 1928.)

Soybean Products

115. **Ground Soybeans** is the product obtained by grinding whole soybeans without cooking or removing any of the oil. (Adopted 1933.)

116.....**Per Cent Protein Soybean Oil Cake or Soybean Oil Chips** is the product obtained by crushing, cooking and removing part of the oil from soybeans. (Adopted 1933.)

117.....**Per Cent Protein Soybean Oil Meal** is ground soybean oil cake or ground soybean oil chips. (Adopted 1933.)

Velvet Bean Products

118. **Velvet Bean Meal** is ground velvet beans containing only an unavoidable trace of hulls or pods. (Adopted prior to 1928.)

119. **Ground Velvet Bean and Pod** is the product derived by grinding velvet beans with the pod. It contains no additional pods or other materials. (Adopted prior to 1928.)

Wheat Products

120. **Wheat Bran** is the coarse outer covering of the wheat kernel as separated from cleaned and scoured wheat in the usual process of commercial milling. (Adopted prior to 1928.)

121. **Standard Middlings** consists mostly of fine particles of bran, germ, and very little of the fibrous offal obtained from the "tail of the mill." This product must be obtained in the usual commercial process of milling and must not contain more than 9.5 per cent of crude fiber. (Adopted prior to 1928.)

122. **Flour Middlings** shall consist of standard middlings and red dog flour combined in the proportions obtained in the usual process of milling and must not contain more than 6.0 per cent of crude fiber. (Adopted prior to 1928.)

123. **Wheat Red Dog** is a by-product obtained in the usual commercial process of flour milling, consisting principally of aleurone with small quantities of flour and fine bran particles and must not contain more than 4.0 per cent of crude fiber. (Adopted prior to 1928.)

124. **Wheat Low-Grade Feed Flour** is a by-product obtained in the usual commercial process of flour milling, consisting principally of flour with small quantities of aleurone and fine bran particles and must not contain more than 1.5 per cent of crude fiber. (Adopted prior to 1928.)

125. **Wheat Bran and Standard Middlings** consists of the two commodities as defined above, mixed in the proportions obtained in the usual process of commercial milling. (Adopted prior to 1928.)

126. **Hard Wheat Mixed Feed** (mill-run wheat feed) consists of pure wheat bran and flour middlings combined in the proportions obtained in the usual process of commercial milling. This product must not contain more than 9.5 per cent of crude fiber. (Adopted prior to 1928.)

127. **Brown Shorts** (Red Shorts) consists mostly of the fine particles of bran, germ and very little of the fibrous offal obtained from the "tail of the mill." This product must be obtained in the usual commercial process of milling and must not contain more than 7.5 per cent of crude fiber. (Adopted prior to 1928.)

128. **Gray Shorts** (Gray Middlings or Total Shorts) consists of the fine particles of the outer bran, the inner bran or bee-wing bran, the germ and the offal or fibrous materials obtained from the "tail of the mill." This product must be obtained in the usual process of commercial milling and must not contain more than 6.0 per cent of crude fiber. (Adopted prior to 1928.)

129. **White Shorts or White Middlings** consists of a small portion of the fine bran particles and the germ and a large portion of the fibrous offal obtained from the "tail of the mill." This product must be obtained in the usual process of flour milling and must not contain more than 3.5 per cent of crude fiber. (Adopted prior to 1928.)

130. **Wheat Mixed Feed** (Mill-run wheat feed) consists of pure wheat bran and the gray or total shorts combined in the proportions obtained in the usual process of commercial milling. This product must not contain more than 8.5 per cent of crude fiber. (Adopted prior to 1928.)

131. **Screenings** consists of the smaller imperfect grains, weed seeds, and other foreign materials, having feed value, separated in cleaning the grain. (Adopted prior to 1928.)

132. **Scouring** consists of such portions of the cuticle, brush, white caps, dust, smut and other materials as are separated from the grain in the usual commercial process of scouring. (Adopted prior to 1928.)

(NOTE) If to any of the wheat or rye by-product feeds there should be added screenings or scourings—as above defined, either ground or unground, bolted or unbolted, such brand shall be so registered, labeled and sold as clearly to indicate this fact. The word "Screenings" or "Scourings" as the case may be, shall appear as part of the name or brand and shall be printed in the same size and face of type as the remainder of the brand name. When the word "Screenings" appears it is not necessary to show also on the labeling the word "Scourings." (Adopted prior to 1928.)

TENTATIVE DEFINITIONS

These definitions have received favorable consideration, but are not official. They are subject to revision before final adoption.

T-1 **Dried Whey** (Feeding) is the by-product from the manufacture of cheese and/or casein. This product shall contain at least 65 per cent of lactose (milk sugar).

T-2 **Spent Bone Black** is the product resulting from the repeated charring of bone black or animal charcoal after use in clarifying sugar solutions. It shall contain at least 11.50 per cent of phosphorous (P).

T-3 **Animal Charcoal or Bone Black** is the product obtained by charring bones in closed retorts, containing not less than 14.75 per cent of phosphorus (P).

T-4 **Stearine** (Feeding) is the solid material obtained by filtration from an oil after chilling or freezing in the process of refining. When this product is sold as a feed, the term shall be prefixed by the name of the oil from which it is obtained.

T-5 **Anti-rachitic Oil** is an oil recognized as a satisfactory source of vitamin D obtained from fish or parts thereof. This term will be recognized only in the declaration of ingredients in a proprietary feed. The name of the specific oil may be used in lieu of this name if desired.

T-6 **Cane Molasses** (Feeding) is a by-product of the manufacture of sugar from cane, and contains 51 per cent or more of sugar expressed as invert sugar, and not more than 8 per cent of ash.

T-7 **Beet Molasses** (Feeding) is a by-product of the manufacture of sugar from sugar beets and contains 52 per cent or more of sugar expressed as invert sugar, and not more than 10 per cent of ash.

T-8 **Iodized Salt** (Feeding) is common salt (NaCl) containing not less than 0.015 per cent of iodine, uniformly distributed.

T-9 **Hominy Feed** is a mixture of corn bran, corn germ and a part of the starchy portion of either white or yellow corn kernels or mixture thereof as produced in the manufacture of pearl hominy, hominy grits or table meal, and shall contain not less than 5 per cent of crude fat. If prefixed with the words "white" or "yellow," the product must correspond thereto.

Resolutions Adopted

1. Resolved that it is the sense of this Association that we understand the term "Nitrogen Free Extract" to cover the product indicated by the percentage obtained by subtracting from 100 per cent the sum of the percentages of Ash, Moisture, Protein, Fat and Fiber. (Adopted prior to 1923.)

2. Resolved that the term "carbohydrates" be interpreted to cover the product indicated by the percentage obtained by the addition of the percentages of crude fibre and nitrogen free extract. (Adopted prior to 1923.)

3. Resolved that it is the sense of this Association that a ton of feed be 2,000 pounds, net. (Adopted prior to 1923.)

4. Resolved that this Association go on record as opposing the use of second hand bags unless they are turned wrong side out so that the original stenciling will not be displayed. (Adopted prior to 1923.)

5. Resolved that the Association go on record to the effect that the term cracked corn does not apply to degermed cracked corn. (Adopted prior to 1923.)

6. Resolved that this Association go on record as condemning the practice of packing feedings stuffs in bags containing 99 pounds net and billing and charging for 100 pounds net. (Adopted 1923.)

7. Whereas, Linseed Oil Meal is sold more or less on the basis of the protein content, as in the case of cottonseed meal, therefore,

Be it Resolved, that the percentage of protein should be prefixed to linseed cake or meal, as is done with cottonseed meal, for example 34 per cent Protein Linseed Meal. (Adopted 1923.)

8. Resolved that it is the sense of this Association that no product sold under a trade or proprietary name be recognized for the purpose of formulating definitions, standards, etc. (Adopted 1927.)

9. Resolved that this Association go on record as condemning the use of the word vitamin in a brand name, and as opposing the acceptance of registration of feeds with this word in the brand name. (Adopted 1929.)

10. Resolved: (a) That it is the sense of this Association that the names of feed materials or their combinations must not be misleading as to the kind, character and nature of the material or materials.

(b) That the name of each feed material should be stated in its simplest form and in the common English term, if such term exists, omitting all superflous or ambiguous words.

(c) That if a descriptive name is used, the material must correspond thereto. (Adopted 1930.)

11. Resolved that this Association go on record as disapproving any use of artificial colors in the manufacture of feedstuffs. (Adopted 1931.)

12. Resolved that this Association go on record as condemning the use of any contraction of the word "vitamin," or any word suggesting vitamin in a brand name, and as opposing the acceptance of registrations of feeds under names which are in conflict with this resolution. (Adopted 1932.)

13. Resolved that any material sold primarily as a vitamin D supplement for poultry shall be labeled with a minimum guarantee of anti-rachitic potency, specifying the minimum percentage level at which normal calcification is produced, according to the tentative method of analysis as adopted by the Association of Official Agricultural Chemists. (Adopted 1933.)

14. Resolved that all tentative definitions should not be used until adopted as official, unless specified action of the Association is taken. (Adopted 1933.)

Table 4.—Estimated Sales of Commercial Feeding Stuffs in Indiana

KIND OF FEED	Estimated Tons			Estimated Retail Values, Dollars	
	1931	1932	1933	1932	1933
Alfalfa meal and leaf meal	3,906	2,906	3,125	86,599	89,688
Animal by-products (Tankage, meat scraps, etc.)	32,719	35,656	38,531	1,030,458	1,392,896
Brewers', distillers' and yeast dried grains	63	94	1,750	1,880	40,513
Condimental poultry and stock feeds*	1,156	594	625	63,855	90,625

UNIVERSITY OF ARIZONA LIBRARY

Circular No. 202 May, 1934

COMMERCIAL FERTILIZERS

UNIVERSITY OF ARIZONA
LIBRARY

The effect of fertilizer versus no fertilizer application. Dark rows, fertilizer drill holes were stopped up and no fertilizer was applied. Light rows, fertilizer drill holes were clear and fertilizer was applied.

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

This circular gives a summary of the inspection of commercial fertilizers for the year 1933. The inspectors visited every county in the state in both the spring and the fall season and collected 1,153 official samples.

The Indiana Fertilizer Law is essentially a correct labeling act. It protects the honest and efficient manufacturer, dealer and agent as well as the consumer. In order to obtain maximum protection the consumer must read carefully and understand thoroughly the information on the state tag.

Refunds amounting to $263.43 were paid by 17 manufacturers on 47 shipments of fertilizer deficient in analysis.

Table 1 shows the average composition of the common fertilizer materials.

Table 3 shows the tonnages of the different analyses for which there was the greatest demand. The tonnage sales of 2-12-6 amounted to over 37 per cent of all the fertilizer sold. Over 86 per cent of the total tonnage was confined to 33 analyses, while less than 14 per cent was divided among 110 different grades.

The average content of actual plant food of all the fertilizer sold in 1933 was 460 pounds per ton. The average analysis was 2.1 per cent nitrogen, 13.2 per cent available phosphoric acid and 6.6 per cent water soluble potash.

Table 6 gives the tonnage sales of low and high analysis fertilizers for the past 19 years.

Due to lack of funds, the table giving the analysis of individual samples is omitted from the report this year. It is the intention to resume publication of this table in future reports as soon as funds are available.

COMMERCIAL FERTILIZERS

H. R. Kraybill, *State Chemist*
O. W. Ford, *Assistant Chemist* O. S. Roberts, *Chief Inspector*
Assistant Chemists, L. E. Horat, M. H. Thornton
Inspectors, C. M. Cohee, J. W. Jackman

The Indiana Fertilizer Law is essentially a correct labeling act. The intent of the law is not to determine what type of fertilizer may be sold. The law is designed to furnish the purchaser with a true statement of certain information on the state tag that will enable him to decide whether or not the fertilizer is the type that will meet his needs. The state tag gives a statement of the percentages of total nitrogen, total or available phosphoric acid, and water soluble potash. With this information available the purchaser should be able to judge whether the fertilizer offered for sale meets his requirements. *In order to do this the consumer must read carefully and understand thoroughly the information on the state tag.*

The Indiana Fertilizer Law protects the honest and efficient manufacturer, dealer and agent, as well as the consumer. Full cooperation on the part of the manufacturer, dealer, agent and consumer is necessary in order to accomplish the purpose of the law.

A copy of the full text of the law will be sent to persons making requests for the same to the State Chemist, Purdue University Agricultural Experiment Station, Lafayette, Indiana.

This circular presents the results of the inspection of commercial fertilizers sold in Indiana during 1933. From the sale of tags it is estimated that 99,755 tons of fertilizer were sold, while from manufacturers' reports a tonnage of 105,289 is indicated. It is believed that the latter figure represents more nearly the actual tonnage. The difference between the two estimates is apparently due to the fact that the manufacturers reduced their stocks of tags on hand during the year. This indicates that the tonnage in 1933 was about five per cent higher than in 1932.

Inspectors from the department visited every county in the state in both the spring and fall seasons and collected 1,153 official samples of fertilizer. One sample was drawn for approximately each 90 tons of fertilizer that were sold. Of these samples, 1,064 were equal to or above the guarantee in value; 84 were within 10 per cent of the guaranteed value and 5 were 10 per cent or more below the guaranteed value. Eleven of the 790 samples which contained nitrogen showed the presence of inferior nitrogen, of which four were dried manure and four were muck. Both of these materials are inferior sources of nitrogen.

REFUNDS

Every year a few cases of deficiencies occur, due to errors in labeling the fertilizer. This results from carelessness on the part of the person responsible for attaching the tags. Manufacturers should guard against such errors.

When deficiencies in analysis amounting to $1.00 or more per ton on raw materials, as calculated from the wholesale price, are found, refunds are calculated and indicated on the report of the analysis which is sent to the manufacturer and to the consumer. Refunds on mixed fertilizers are usually calculated when one ingredient is deficient to the extent of $1.00 or more per ton, regardless of the excess in amounts of the other ingredients. Nitrogen, phosphoric acid and potash play definite roles in crop production. An excess of one ingredient will not necessarily compensate for a deficiency of another.

All refunds are required to be distributed to the consumer wherever possible, and receipts for the same must be filed with the State Chemist. In case there are no records as to the consumer, the refunds may be turned over to a local charitable organization, but receipts for the same must be filed with the State Chemist.

The payment of a refund by the manufacturer to the consumer does not remove the violation, but it does indicate good intentions on the part of the manufacturer and shows his willingness to do what he can to correct the violation. However, the payment of the refund does not nullify the right of anyone in the state to call a deficiency of analysis to the attention of the prosecuting attorney.

Refunds amounting to $263.43 were paid by 17 manufacturers on 47 shipments of deficient fertilizer in 1933.

MANUFACTURERS

The term "Commercial Fertilizer" is defined by law to include all materials used for manurial purposes except barnyard manure, marl, lime, wood ashes and plaster. Barnyard manure, sheep manure and muck when dried or processed in any way come under the provisions of the law. Before any commercial fertilizer is exposed or offered for sale or sold in the state it is necessary to register the fertilizer with the State Chemist and tag it properly with Indiana state tags or labels. Bulk shipments must be accompanied with sufficient labels to cover the total weight of the material.

Manufacturers should not ship fertilizer without having it properly tagged with Indiana state tags. Experience has shown that when this is done it is difficult to avoid the sale of untagged fertilizer. The State Chemist has no authority to grant permission to a manufacturer to ship unlabeled fertilizer.

AGENTS, DEALERS AND DISTRIBUTORS

Agents should familiarize themselves with the provisions of the Indiana Fertilizer Law. Each package of fertilizer offered or exposed for sale or sold in Indiana must have attached to it the Indiana state tag bearing the facsimile signature of the State Chemist (see reproduction, page 8). *In case you receive a car of untagged fertilizer, wire the manufacturer for tags and notify the State Chemist. Do not accept the shipment until proper tags are furnished.*

Since local agents are responsible for the fertilizer that they offer for sale they should deal only with those manufacturers who agree to assume full responsibility in cases where the fertilizer fails to meet the requirements of the law.

When inspection reports show that fertilizer in your possession is deficient enough so that a refund is calculated on it, withdraw it from sale at once and notify the State Chemist, giving the date and the amount withdrawn from sale.

CONSUMERS

The Indiana state tag is your guarantee of the fertilizer that you purchase. Read the tag. Let the analysis on the state tag be your guide rather than the brand name. Refuse to accept any fertilizer which does not have the Indiana state tag attached to each package.

When analysis of a fertilizer is desired, do not forward a sample, but notify the State Chemist, telling how much you have on hand and send in a copy of the official label which is attached to the fertilizer.

Purchase the type of fertilizer that will meet the plant food requirements of your crops. Consult Circular No. 162 of the Purdue University Agricultural Experiment Station, entitled "Fertilizers for Indiana Soils and Crops."

CAUTION

The consumer should remember that the presence of the Indiana state label with the facsimile signature of the State Chemist does not mean that the State Chemist recommends the fertilizer. Poor quality fertilizer may be sold legally, provided it is correctly labeled. The consumer should be guided by the analysis of the fertilizer.

MEANING OF ANALYSIS

Nitrogen.—In 1881 when the Indiana Fertilizer Law was passed the principal source of nitrogen was from organic materials. The nitrogen was derived largely from such products as dried blood, bone, tankage and slaughter house by-products, garbage tankage, cotton seed meal, castor pomace, tobacco stems, manure sweepings and dried peat. Although there is little water soluble nitrogen in the above products, all carry a good source of nitrogen with the exception of garbage tankage, manure sweepings, spent tobacco stems and dried peat. In more recent years most of the animal products have been diverted into the mixed feed channels, and water soluble forms of nitrogen have taken their place in fertilizer mixtures. Today we find that most of the nitrogen carrying fertilizers have more than 80 per cent of their nitrogen content in some water soluble form.

A few of the sources of water soluble forms of nitrogen are as follows: nitrate of soda (natural and synthetic), ammonium sulphate, cal-urea, cal-nitro, urea, cyanamid and calcium nitrate.

Since water soluble forms of nitrogen are considered as readily available for plant growth, we class a fertilizer as satisfactory that has 60 per cent of its guaranteed nitrogen in water soluble form.

If less than 60 per cent of its guaranteed nitrogen is water soluble, then the availability of the insoluble organic nitrogen is determined by the alkaline permanganate method. In this case, if the active water insoluble nitrogen is equal to or greater than the inactive, the nitrogen is classed as satisfactory. If less than half of the insoluble nitrogen is active, the nitrogen is classed as inferior.

Manures and garbage tankages that have not been acidulated show an inferior quality of nitrogen. This is not the fault of the manufacturer when they are sold as manure and garbage tankage.

Phosphoric Acid.—The phosphorus in the fertilizer is linked up as chemical compounds with calcium, iron and aluminum. It may be present as mono-, di- or tricalcium phosphate.

As monocalcium phosphate $CaH_4\ (PO_4)_2$ it is water soluble and readily available to plants for growth.

As dicalcium phosphate $Ca_2H_2\ (PO_4)_2$ it is soluble in the soil solution and rendered available to plants for growth.

As tricalcium phosphate $Ca_3\ (PO_4)_2$ it is somewhat less available to plants.

As a complex tricalcium phosphate combined with fluorine and lime (raw rock phosphate) it is much less available to plants and becomes available only slowly in the soil.

The bulk of the fertilizer sold today contains mixtures of large amounts of mono- and dicalcium phosphate and some tricalcium phosphate. This is in contrast to the earlier years when most of the fertilizer used was bone where the phosphorus is present as tricalcium phosphate.

In acidulated goods the phosphorus is sold only on the basis of the available phosphoric acid (P_2O_5) content. The available is the sum of the soluble and reverted phosphoric acid (P_2O_5).

In bone and rock phosphate, when sold as such, the phosphorus is sold only on the basis of the total phosphoric acid (P_2O_5) content. It is only fair to state, however, that about 60 to 75 per cent of the total phosphoric acid (P_2O_5) content of bone is available by the neutral ammonium citrate method, while only from three to six per cent of the total phosphoric acid (P_2O_5) of rock phosphate is available by the same method.

Potash.—Potash, as the official label states, must be soluble in water, in which form it is considered directly available for plant use.

No difference in crop growth has been noted in American, French or German potash. Muriate of potash (KCl) being the cheapest has largely supplanted other potash salts for general crops.

AVERAGE COMPOSITION OF FERTILIZER MATERIALS

Table 1 gives the average composition of some of the more common fertilizer materials.

TABLE 1. Average Composition and Comparative Evaluation of the Common Fertilizing Materials

Material	Nitrogen Per Cents							Phosphoric Acid Per Cents			Water Soluble Potash Per Cent	Comparative Value Per Ton
	Total	Water Soluble Organic	Water Soluble Ammonia	Water Soluble Nitrate	Water Insoluble Organic	Active Insoluble Organic	Inactive Insoluble Organic	Total	Insoluble	Available

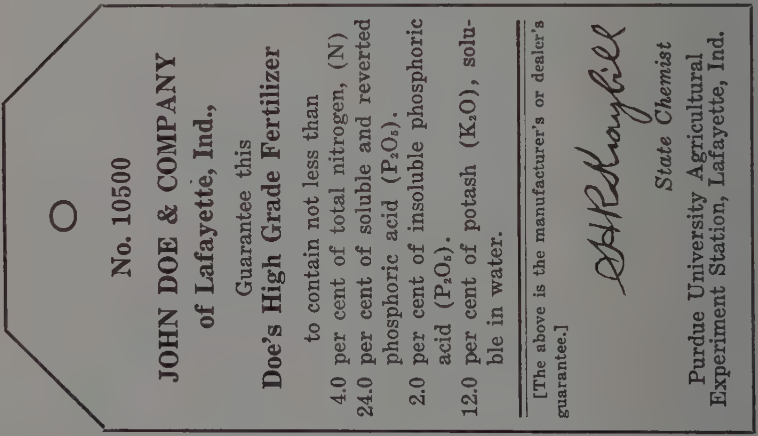
OFFICIAL STATE LABEL



No. 10500

JOHN DOE & COMPANY
of Lafayette, Ind.,

Guarantee this
Doe's High Grade Fertilizer

to contain not less than
4.0 per cent of total nitrogen, (N)
24.0 per cent of soluble and reverted phosphoric acid (P_2O_5).
2.0 per cent of insoluble phosphoric acid (P_2O_5).
12.0 per cent of potash (K_2O), soluble in water.

[The above is the manufacturer's or dealer's guarantee.]

H R Kraybill
State Chemist

Purdue University Agricultural
Experiment Station, Lafayette, Ind.

The only label recognized under the law is that bearing the facsimile signature of the State Chemist. (See reproduction.) The label as issued is always printed and contains all the facts required by law; any alteration thereon constitutes a violation of the law.

Label No. 10500 guarantees that each 100 pounds of fertilizer will contain at least 4.0 pounds of total nitrogen (N), 24.0 pounds of soluble and reverted phosphoric acid (P_2O_5), and 2.0 pounds of insoluble phosphoric acid (P_2O_5), and 12.0 pounds of water soluble potash (K_2O).

We hope that it will not again be necessary to file affidavits against agents for distributing unlabeled fertilizer. There can be no excuse for shipping unlabeled fertilizer. Agents receiving same should protect themselves by refusing to accept the car. Wire the manufacturer for official labels and write the State Chemist fully concerning the unlabeled shipment.

MANY GRADES UNNECESSARY

Table 3 shows the tonnage of fertilizer sold under the different grades of analyses. In 1933 over 86 per cent of the tonnage is represented by 33 grades, while less than 14 per cent were distributed over 110 analyses. Considerable saving could be made by the manufacturer if the number of grades were reduced materially.

E. Bone Products (Steam and Raw Bone)—430.
F. Miscellaneous—303.

Summary—
1. Total tons reported—101,075.
2. Tag sales from firms not reporting—4,214.
3. Total tonnage based on reports (Items 1 and 2)—105,289.
4. Total tonnage from tag sales—99,755.

*A—Available P_2O_5; I—Insoluble P_2O_5.

Table 5 gives the total tonnage, retail price, cost per ton, pounds of actual plant food per ton and the cost per pound of plant food for the past 13 years. It will be noted that the average cost per pound of plant food is lower in 1933 than for any year since 1920.

TABLE 5. Tonnage, Retail Value and Pounds Per Ton of Plant Food

1929	1,378	854	1,217	155	6
1930	1,421	1,090	1,320	89	10
1931	1,396	1,100	1,315	74	7
1932	1,138	835	1,053	80	5
1933	1,153	829	1,064	84	5

PRICES USED IN SECURING COMPARATIVE VALUE OF FERTILIZERS

These values are not for the purpose of fixing the commercial value of mixed fertilizers, but are for comparative purposes only. They are for use in comparing the value of inspection samples with manufacturers' guarantees, and can be used advantageously by fertilizer purchasers in calculating the relative values of various brands offered for sale by different manufacturers.

For use in determining the comparative values of fertilizer inspected in 1934 the following prices have been adopted:

TABLE 9. Prices Used in Determining Comparative Values of Fertilizers

	Per pound cents	Per unit or per cent dollars
All fertilizers—		
Nitrogen (N)	10.0	2.00
Potash (K_2O) soluble in water	5.0	1.00
Soluble and reverted phosphoric acid (P_2O_5)	5.0	1.00
Mixed fertilizers containing nitrogen—		
Insoluble phosphoric acid (P_2O_5)	1.5	0.30
Precipitated bone—		
Available phosphoric acid (P_2O_5)	5.0	1.00
Insoluble phosphoric acid (P_2O_5)	1.5	0.30
Animal by-products, bone, tankage, etc.—		
Total phosphoric acid (P_2O_5)	3.5	0.70
Basic Slag—		
Total phosphoric acid (P_2O_5)	4.5	0.90
Rock phosphate (floats) and low grade slag—		
Total phosphoric acid (P_2O_5)	1.5	0.30
Mixed fertilizer, acid phosphate, etc., containing no nitrogen—		
Insoluble phosphoric acid	.0	0.00

Table 10 gives the fertilizer tonnage for the spring and fall seasons as well as the total tonnage and estimated retail value for the year 1933.

TABLE 10. Fertilizer Tonnage and Estimated Retail Value, 1933

Class of Fertilizer	Spring 1933 Tons	Fall 1933 Tons	Total 1933 Tons	Estimated 1933 Retail Value
1. Acid phosphate, 14% and less		219	219	$4,677.84
2. Acid phosphate, 16%	844	2,875	3,719	74,305.62
3. Acid phosphate, 18-20%	844	6,344	7,188	168,486.72
4. Acid phosphate above 20%	94	94	188	6,236.56
7. Ammoniated superphosphate*	188		188	7,995.50
10. Acid phosphate and potash, 14-19 units	156	500	656	16,104.80
10a. Acid phosphate and potash above 20 units	6,125	2,969	9,094	270,091.80
11. Complete fertilizer (low)	125	531	656	21,405.28
12. Complete fertilizer (medium)	1,156	1,469	2,625	54,757.50
13. Complete fertilizer (high)	6,141	17,360	23,501	628,181.73
13a. Complete fertilizer above 20 units	22,225	24,888	47,113	1,427,523.90
14. Steamed bone	94	125	219	7,227.00
15. Raw bone	131	407	538	10,760.00
16. Tankage	313	125	438	6,570.00
21. Rock phosphate*		63	63	945.00
22. Nitrogen salts**	1,200	350	1,550	57,009.00
†Ammonium sulphate	900	50	950	
†Nitrate of soda	250	100	350	
†Cyanamid	50	200	250	
23. Potash salts**	1,100		1,100	50,468.00
†Muriate of potash	1,100		1,100	
†Sulphate of potash				
†Kainit				
31. Miscellaneous (peat, dried manure, dried blood, garbage tankage, etc.)	606	94	700	19,460.00
Total	41,342	58,413	99,755	$2,851,674.25

* Retail values estimated from average analyses obtained from tag sales and the comparative values of circular 196, p. 13.

** Tonnage in these classes estimated on the basis of 200-pound bags or 10 bags per ton. All other classes estimated on the basis of 125-pound bags or 16 bags per ton.

† Not included in totals.

Table 11 gives a summary of inspection on the basis of guaranteed and found composition and retail values, while Table 12 gives the standing of the manufacturers as determined by the inspection of 1933.

TABLE 11. Summary of Inspection on the Basis of Composition, Guaranteed, Found, and Retail Values

Class of Fertilizer	Number of Samples	Nitrogen (N), average per cent.		Available phosphoric acid (P_2O_5), average per cent.		Insoluble phosphoric acid (P_2O_5), average per cent.		Total phosphoric acid (P_2O_5), average per cent.		Potash (K_2O), soluble in water average per cent.		Comparative value per ton dollars		Retail price per ton, average, dollars	Comparison, retail price and found comparative value per ton, dollars	Range in retail price per ton, dollars

Circular No. 203 June, 1934

REPORT OF
MOSES FELL ANNEX FARM
BEDFORD, INDIANA

JUNE, 1934

RSITY OF
RARY

"In order to give permanent and lasting recognition and testimony in appreciation of their service to agriculture and country life, and to the people of Lawrence County, Southern Indiana, and the State of Indiana, this gateway was erected by Purdue University in memory of Moses Fell Dunn and Antoinette Fell."

—Director J. H. Skinner.

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

The Moses Fell Annex Farm consisting of 479 acres was received from the Honorable Moses F. Dunn and Antoinette Fell in 1914, and is used by the Purdue University Agricultural Experiment Station for the purpose of making a thorough study of the agricultural problems of southern Indiana. Mr. Dunn not only gave the farm but generously provided for its development so that it might be operated without cost to the taxpayers of the State.

The farm is being operated for the benefit of the farmers of this section. The soil type represents a very large section in the southern part of the state and the results of the experimental work may be applied throughout that section.

Purdue University wishes to acknowledge the helpful cooperation of the various Farm Bureaus, the County Agricultural Agents, the banks, the Home Economics Clubs, Kiwanis Clubs, Rotary Clubs, and other organizations and individuals of Lawrence and neighboring counties. This cooperation extends the value and usefulness of the farm.

"After we have done everything that it is possible to do toward improving agriculture as a whole it still will be true that only those who farm intelligently and carefully, who work diligently and save reasonably, can hope to prosper. Those who fall below these standards will make at best but a bare living.

"It is a mistaken notion that when prices are low because of overproduction that the remedy is to take less pains and let the yields of our acres and of our animals run down. Such practice leads to but one end —bankruptcy. Whatever the price, it is the man that makes the highest returns on his acres who is most prosperous. The truth is the lower the price of the product the greater the need for high efficiency in producing it. When prices are high even mediocre yields are profitable, but such yields are always unprofitable when the prices are low. Therefore the more discouraging the price of farm products, the greater the necessity for good farming.

"The surest way to cut production costs is by increasing the yields of our acres and our animals. The farmer who disregards this law cannot be saved by any outside help."

REPORT OF MOSES FELL ANNEX FARM

JUNE, 1934

H. J. Reed, Farm Director H. G. Hall, Local Superintendent

The work on the Moses Fell Annex farm is carried on to answer many important questions that have confronted the farmers of southern Indiana.

What are the most profitable fertilizer applications on this type of soil? Are applications of manure sufficient? What rotations will give the best results? What can be done to make our pasture-lands more productive for live stock? What varieties of the various grain crops will give the most satisfactory yields over a period of years?

Can Korean lespedeza be used in a regular crop rotation? What about sweet clover? How can alfalfa be grown on this land?

What are the principal problems of poultry production?

Can cool storage be satisfactorily used for apples in this section of the state? What is the value of ice in connection with cool storage? How much longer can fall apples be held by using ice? What is the best and most economical method of using ice in such storage? Does such storage aid marketing the crop?

How much fertilizer is necessary for best results with tobacco?

What kind of sheep will fit best into the live stock program of your farm?

Is electric brooding of chicks practical on your farm?

What results will the new spray materials give on fruit trees in this section?

Can the thin lands of this section be made to produce good crops?

What varieties of plums and peaches should be grown here? Do they have a place in the local market?

Can cows give a good milk supply and also produce calves that make good beef?

What is the best time to sow clover seed?

These and hundreds of other pertinent questions are being answered by the results of projects now underway on this farm. Years of continuous and painstaking effort are necessary to give reliable information on such problems.

Regardless of whether the farmer can control or influence the prices of his products, economical and efficient production will always effect his net income.

Marketing is an important phase of our agricultural work today but crops and live stock of high quality must be produced before any marketing plan can operate satisfactorily. It is, therefore, logical that the farmers are interested in farming systems that give the best average returns over a period of years to eliminate the variations of temperature and moisture.

The soils and crops work carried out under the direction of the Department of Agronomy has been under way since 1915, and clearly demonstrates the value of various applications of plant food and the importance of choosing the best varieties for economical crop production.

The investigations being conducted under the Horticultural Department have demonstrated orchard renovation practice, the value and effectiveness of various spray schedules, orchard fertilization, cool storage management and costs, orchard sanitation, removal of arsenical residue from fruit, adaptation of peach and plum varieties, farm garden and many other phases of horticulture that have added to the knowledge of fruit production. The Entomology Department has rendered valuable service in combating orchard insects and timing orchard sprays. The Agricultural Engineering Department has studied the use of electricity on the farm, both in the home and on the farm. The Department of Poultry Husbandry has assisted in developing an outstanding flock of Barred Plymouth Rock chickens which has not only contributed information on flock improvement but has demonstrated good housing, brooding methods, feeding and flock management.

2—49187

The Department of Animal Husbandry is cooperating in a lamb production demonstration that is of interest to sheepmen. A cooperative project is under way to study the milking and beefing qualities of an imported strain of Scotch shorthorn cattle. This work will continue for a long period of years and will yield information on breeding practices that will be of value to breeders of both beef and dairy cattle. Pasture improvement is a matter of economic importance in southern Indiana. The work on this farm is showing that it is possible to improve the carrying capacity of the pasture land and in time a more complete project will be undertaken to coordinate the live stock and pasture work.

The Moses Fell Annex farm serves the farmers of southern Indiana in a very practical way at no cost to the taxpayers of the State. The Hon. Moses F. Dunn and Antoinette Fell gave the farm for this purpose and generously provided for its development so that a long-time constructive effort could be made to develop an agriculture that would improve the land, yield a profit and enrich the state.

SOILS AND CROPS WORK

The soil fertility experiments carried on under the direction of A. T. Wiancko, Chief, and G. P. Walker, Associate, of the Agronomy Department are showing striking results that are of great value to the farmers of southern Indiana.

GENERAL SOIL FERTILITY TEST

The field was laid out and tile drained in the spring of 1917. The original rotation was corn, wheat, clover and timothy, but this was changed in 1923 to corn, soybeans, wheat and clover, which is a more suitable rotation for this kind of land. All crops are removed except on plots 6, 7, 8, 10 and 11, where only the ear corn, wheat grain, soybean grain, and clover hay are removed, leaving all the roughage, except the clover hay on the land in lieu of manure.

The treatments shown in the second column of the table are as follows: L = ground limestone; Res. = crop residue; O = no treatment; M = manure.

All limed plots received 3 tons of ground limestone per acre in the spring of 1917 and an additional 2 tons in 1931. The fertilizers indicated in the table have been applied at the rate of 200 pounds per acre in the row for corn and 400 pounds for wheat since 1929. To the end of 1928 the potash in the fertilizer was 4 per cent and the phosphorus and potash were equally divided between the corn and wheat, but the nitrogen was all applied for wheat, half in the fall and half in the spring.

The manure applications consisted of 6 tons per acre plowed under for corn in the first round of the rotation. Since then the rate of manuring has been equal to the amount of produce removed during the previous round of the rotation except the wheat grain.

Table I shows the results of different soil treatments begun in 1917.

It will be noted, in comparing with earlier reports and in examining the crops on the experiment field, that the spread between the good and poor treatments is becoming greater year by year, and that the better treatments are becoming more and more profitable. Without soil treatment, the average value of the crops per acre per rotation of corn, soybeans, wheat, and clover, is now $23.44 (plot 14). With lime manure and fertilizer, the value is $67.76 at an average cash outlay of $11.70 for lime and fertilizer (plot 19).

The most profitable returns have been secured on the limed land, which has received an average of 6.7 tons of manure for corn and 450 pounds of superphosphate per acre divided between the corn and wheat in the rotation of corn, soybeans, wheat, and clover (plot 18). The crop increases from this treatment have averaged 30.4 bushels of corn; 9.4 bushels of soybeans; 11.6 bushels of wheat; and 1,088 pounds of hay per acre, valued at $43.80 per rotation at a cost of $11.33 for lime and fertilizer.

TABLE I.—RESULTS OF GENERAL FERTILITY TEST

	Av. L checks	25.4	8.6	5.2	1316	32.04	....	....	....

NOTE.—In computing the financial results, corn has been valued at 50c, wheat at 80c and soybeans at $1.00 per bushel; and hay at $10.00 per ton. Straw and stover have not been counted. Nitrogen has been charged at 10c, phosphoric acid at 7c and potash at 7c per pound. Ground limestone has been charged at $2.50 per ton. Manure has been charged at 50c and residues at $1.00 per ton for spreading on the land.

Phosphorus is by far the most important plant food need of this soil. Applications of superphosphate have been highly profitable, either alone or in addition to manure. Without manure (plot 2) 225 pounds of 16 per cent superphosphate for corn and wheat in the four-year rotation has produced average crop increases of 16.0 bushels of corn, 5.5 bushels of soybeans, 8.4 bushels of wheat and 1,164 pounds of hay per acre, valued at $33.93 at a cost of $5.04 for the fertilizer. On land receiving an average of 6.7 tons of manure for corn, a similar use of superphosphate has further increased the crop yields by 14.1 bushels of corn, 5.7 bushels of soybeans, 7.4 bushels of wheat and 1,191 pounds of hay, valued at $22.40 at a cost of $5.04 for the phosphate, showing that manure is not sufficient on this land. (Compare plots 16 and 18).

In recent years, however, potash has become increasingly important on the land which has been receiving only phosphate, showing that the available supply of potash has been so reduced that it has become a limiting factor. It is showing up particularly on the corn and hay. During the last round of the rotation corn has averaged 6.4 bushels more and hay 326 pounds more on plot 3 than on plot 2.

Manure applied at an average rate of 4.8 tons per acre for the corn has produced average crop increases of 16.3 bushels of corn, 2.1 bushels of soybeans, 2.1 bushels of wheat and 425 pounds of mixed hay per acre, valued at $13.91, which amounts to an average return of $2.90 per ton of manure applied. (Compare plots 14 and 15).

Ground limestone applied at the rate of three tons per acre in 1917 and 2 tons in 1931 has so far produced average crop increases of 5.0 bushels of corn, 1.4 bushels of soybeans, 1.8 bushels of wheat, and 523 pounds of mixed hay per acre, valued at $33.62, up to the present time. (Compare plots 13 and 14.)

Lime and manure together have produced average increases of 21.1 bushels of corn, 3.7 bushels of soybeans, 4.2 bushels of wheat, and 789 pounds of mixed hay per acre, amounting to $21.40 for the rotation. (Compare plots 14 and 16.)

Phosphate and potash on the corn and complete fertilizer on the wheat have produced average increases of 20.0 bushels of corn, 4.3 bushels of soybeans, 10.4 bushels of wheat, and 1,309 pounds of mixed hay per acre, amounting to $29.10 at a total cost of $8.76 for the fertilizer. (Compare plots 12 and 14.)

TOP-DRESSING WHEAT WITH NITROGEN

Beginning with 1928, the wheat on the west ends of plots 4, 6, 12 and 20 of the General Fertility Test has been given a spring top-dressing of 15 pounds of nitrogen per acre. The average results for the five years are shown in the following table:

TABLE II.—RESULTS OF TOP-DRESSING WHEAT WITH NITROGEN IN SPRING

Plot No.	Treatment	Bushels wheat per acre 1928-1933	Bushels increase due to spring top-dressing
4 east end	2-12-6 in fall	15.3	....
4 west end	2-12-6 in fall + 15 lb. N in April	21.6	+6.3
6 east end	2 12-6 in fall	16.9	....
6 west end	2-12-6 in fall + 15 lb. N in April	23.2	6.3
12 east end	2-12-6 in fall	13.0	....
12 west end	2-12-6 in fall + 15 lb. N in April	19.3	6.3
20 east end	2-12-6 in fall	18.6	....
20 west end	2-12-6 in fall + 15 lb. N in April	24.3	5.7

Top-dressing the wheat with 15 pounds of nitrogen per acre in April has increased the yields by 5.7 to 6.3 bushels per acre. This increase has averaged one bushel of wheat for each 2.5 pounds of nitrogen applied. With nitrogen at 10 cents per pound, the increase in yield has been secured at a cost of 25 cents per bushel.

COMPARISON OF DIFFERENT PHOSPHATES

The object of this experiment is to determine the relative values of superphosphate, rock phosphate, bone meal, and basic slag as phosphatic fertilizers. Superphosphate and rock phosphate are also compared in several different proportions with and without lime, manure, nitrogen and potash fertilizers.

This field was laid out and tile drained in the summer of 1915. The crop rotation is corn, wheat and clover with all produce removed, except second growth clover.

The treatments shown in the second column of the table are as follows: L = ground limestone; M = manure; St.B. = steamed bone meal; BS = basic slag; SP = superphosphate; RP = rock phosphate; N = 12 pounds nitrogen; K = 50 pounds potash.

Ground limestone was applied at the rate of 4 tons per acre in 1915 and an additional 2 tons in 1931.

Manure was applied at the rate of 6 tons per acre for corn in the first round of the rotation and since then in amounts equal to the produce removed except wheat grain. The phosphates are applied at the rate shown in the third column in Table III. The rock phosphate is plowed under for corn and the other phosphates, and the nitrogen and potash are broadcast and harrowed in before planting. The following table shows the results to date of treatments begun in 1916.

TABLE III.—RESULTS OF PHOSPHATE EXPERIMENT

Plot No.	Treatment	Pounds phos. acid per acre	Average Yields Per Acre			Financial Statement Per Rotation

1. Plot 13 was manured on Series B in 1916 and Series C in 1917.
2. Plots 17, 18, 20, and 21 receive 12 pounds of nitrogen and 50 pounds of potash per acre per rotation, all on the corn.
3. Applied in 1916 and again in 1925.

NOTE.—In computing the financial results, corn has been valued at 50c, and wheat at 80c per bushel and hay at $10.00 per ton. Straw and stover have not been counted. Nitrogen has been charged at 10c, phosphoric acid at 7c and potash at 7c per pound. Rock phosphate (30%) has been charged at $15.00, and ground limestone at $2.50 per ton. Manure has been charged at 50c per ton for spreading on the land.

The largest returns have been secured from the combination of ground limestone, manure and medium to heavy applications of superphosphate (plots 5 and 26). The heavy treatment (plot 26) has produced average increases of 26.2 bushels of corn, 10.8 bushels of wheat, and 1,733 pounds of mixed hay per acre over the average of the untreated land. (Compare plot 26 with 33.)

In combination with lime and manure, superphosphate has been the most profitable source of phosphorus. (Compare plots 5, 3, 2 and 6.) In this comparison, superphosphate, basic slag and steamed bone meal have been applied at the rate of 48 pounds and rock phosphate at 192 pounds of phosphoric acid per acre with manure for each corn crop.

On limed land, superphosphate has been more efficient than rock phosphate in all cases, whether used in large or small amounts, and with or without manure or nitrogen and potash (compare plots 5, 11, 17, 23, 26 and 29 with plots 6, 12, 18, 24, 27 and 30).

On manured land without lime, rock phosphate has been slightly more profitable than superphosphate (compare plots 8 and 9).

VARIETY TESTS OF FARM CROPS

The selection of hardy, high-yielding varieties of the crops grown in any section is very important. To determine those best adapted for this part of the state, the most promising varieties of several crops have been compared each year for a number of years. Each variety has been harvested separately and the yields determined by weight. The land on which the variety tests are carried has been kept in a good state of fertility by uniform applications of fertilizer on wheat, and manure on each corn crop.

PASTURE EXPERIMENTS

The improvement of pasture land has a very definite place in the agricultural program for southern Indiana. Large areas of this section are better adapted to pasture purposes than to its present use. There is a considerable area of pasture land that is not producing in a satisfactory way. The development of better pastures will make possible the expansion of the livestock industry from both the beef cattle and the dairy cattle point of view.

Several years ago a series of pasture plots was laid out in one section of the old pasture, and the results of soil treatment are given in the following table.

Grass mixtures including timothy, red top, Kentucky blue grass, orchard grass, alsike clover, sweet clover, alfalfa and lespedeza were seeded on the plots in April, 1924. The first 2 years' growth was largely alsike clover, timothy and red top with scattered clumps of orchard grass, sweet clover and alfalfa.

A plot in the clover seed strain test which was practically killed out by the winter weather. Notice the excellent growth of surrounding clover. This emphasizes the importance of using hardy strains of red clover.

BETTER PASTURES

After 10 years blue grass and red top persist along with some timothy on the fertilized plots. Blue grass is much better on the limed and phosphated areas than on the unlimed. Most of the lespedeza, both Korean and common, seemed to have disappeared in the extreme drouth of 1930 but is slowly coming back. Hop clover, a member of the clover family, gradually came into the mixtures. This early growing legume seems to have some real worth for rolling pasture land of this type.

For new pasture seedings a mixture of timothy, red top, blue grass, alsike clover and lespedeza is recommended for rolling limestone land. On sour thin land, a mixture of lespedeza and red top seems best.

TABLE V.—RESULTS OF PASTURE EXPERIMENT, 1924-1933

Plot No.	Treatment Per Acre*	Green forage pounds per acre 1924	Green forage increase over untreated	1925	Cured forage, pounds per acre average 1926-33	Cured forage, increase over untreated
1	Manure	5445	1512	Due to dry weather growth was small in 1925 and nothing was harvested	1443	473
2	500 lb. 2-12-6	16940	13007		2262	1292
3	500 lb. 0-12-6	13613	9680		1716	746
4	500 lb. 0-12-0	13310	9377		1609	639
5	Untreated	3933	....		970	....
6	Limestone, 2 tons	6363	2430		1421	451
7	Lime, 500 lb. 0-12-0	13613	9680		1665	695
8	Lime, 500 lb. 0-12-6	18150	14217		1786	816
9	Lime, 500 lb. 2-12-6	16940	13007		2437	1467
10	Lime, manure	13613	9860		1715	745

* Treatments applied at seeding time in April, 1923, and fertilizer repeated in fall of 1929. Plots 2 and 9 receive top-dressings of 100 pounds of nitrate of soda per acre each spring. Manure is applied each five years.

ROTATION EXPERIMENT

A comparison of clover, alfalfa, sweet clover, Korean lespedeza and timothy in rotation with corn and wheat is being made on 17 quarter acre plots.

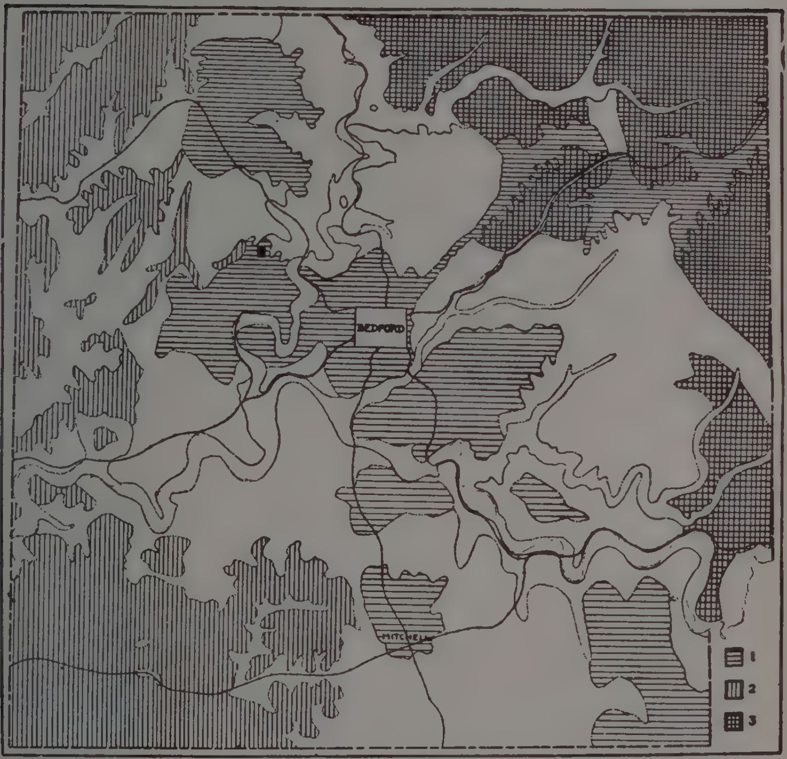
The effect of these crops on succeeding grain crops, their adaptation and dependability as one year rotation crops and their productive capacity are being studied.

All wheat receives 300 pounds per acre of 2-12-6 fertilizer and corn 100 pounds of 0-12-6 in the row. Manure equal to the total weight of produce (except wheat grain) in the previous round of the rotation is divided between corn and wheat.

The rotations under comparison are:

1. Corn, wheat, timothy (hay)
2. Corn, wheat, clover (hay)
3. Corn, wheat, alfalfa (hay)
4. Corn, wheat, sweet clover (seed)
5. Corn, wheat, (sweet clover intercrop)
6. Corn, wheat, Korean lespedeza (hay and seed).

Map Showing Soil Types Similar to Experiment Field



Region	**Principal Soil Characteristics**
No. 1.	**Yellowish limestone land like Bedford experimental field.**
No. 2.	**Yellowish "freestone" land.**
No. 3.	**Like No. 1 on ridge tops and like No. 2 on lower slopes.**

The results of the Moses Fell Annex Farm can be applied to the greater part of Lawrence County and surrounding territory.

The soil survey made in this county in 1922 enabled the Department of Agronomy to classify the soils of this section and to indicate the types which can benefit most from the experimental work on this farm.

The results will apply to all similar land in the county, which is indicated by shading No. 1 on the map. They will also apply fully as well to the areas indicated by shading No. 2, and more or less fully to the areas indicated by shading No. 3 where the hilltops are like No. 1 and the lower slopes like No. 2.

Portions of the unshaded area would doubtless respond to similar treatments, but most of it does not need either lime or fertilizer to the same extent as the shaded areas.

HORTICULTURAL WORK

The results of Horticultural investigational work at Lafayette are often not applicable to southern Indiana conditions. Consequently, numerous projects of interest to fruit growers and home gardeners are being conducted at Moses Fell Annex with a portion of the farm funds. This work is being carried on by members of the Horticultural staff under the direction of Professor Laurenz Greene, assisted by Professor C. L. Burkholder and Professor F. C. Gaylord.

Plum and Prune Variety Tests

This block of approximately 30 varieties has been selected out, so that those varieties now remaining have come through the 1931, 1932, and 1933-34 low winter temperatures without fruit bud injury. During this three year period the variety block of peaches has been almost a total failure. The late spring freeze of 26 degrees on the night of April 27, 1934, destroyed a part of the plum bloom, but enough are still left on some varieties for more than a half crop. The variety susceptibility to low temperatures in bloom will be of special interest in 1934.

Stationary vs. Portable Spraying

This work was started in 1931 with a new portable sprayer being used on one half of the orchard and a new stationary sprayer on the other half. It has been found that, regardless of the year or number of gallons of material applied in each area, labor and power costs alone are twice as high for portable spraying, averaging one-fourth cent per gallon for stationary spraying and a little over one-half cent per gallon for portable spraying. When labor, power, depreciation, and interest on investment charges are all included, there was a saving for the stationary method of $0.002 cent per gallon or $224.00 per year, based on 112,000 gallons of spray. The present stationary pump tank and power unit is large enough to handle the entire orchard, and the cost per gallon would be reduced if the equipment was used to full capacity.

Apple Washer and Apple Sizer Costs

Records of the entire cost of washing apples in a Bean Brush type washer have been kept for three years. A summary of results follows:

Year	*No. of orchard crates*	*Dep. & int. on investment*	*Repairs and replacements*	*Cost of acid, labor, and electric power*	*Cost per bushel*
1931	15,948	$126.00	$14.00	$34.65	$0.0109
1932	7,600	126.00	14.00	16.24	0.0210
1933	14,105	126.00	14.00	27.42	0.0118

Records have been kept on the electric power costs of operating the apple sizing machine. The average cost per 100 crates of fruit has been $0.027, and electric power costs for the apple washer $0.047 per 100 crates.

Codling Moth Control

Each year a different program of sprays is applied over the entire apple orchard in an effort to test out recent developments along insecticide and fungicide lines. In 1934, from one-fourth per cent to three-fourths per cent of oil, plus arsenate of lead, is being used in three first and two second brood covers. The north half of the orchard will receive home made oil emulsion, while a commercial summer oil will be used on the south half.

All trees have been scraped and will be banded with hot dipped beta-naphthol bands to catch the larva of summer broods of codling moth. The

Heavy applications of mulch were placed under many of the trees last summer.

packing shed and loft have been made moth tight, and are kept closed until the day of the June picnic each year. The experimental spray program followed in 1933 did not give satisfactory codling moth control and resulted in a heavy increase in codling moth population.

Apple Washing

The 1933 spray schedule in which two first brood sprays of arsenate of lead and linseed oil was followed by one second brood spray of calcium arsenate

The Elberta peach orchard after pruning. The severe winter killed the fruit buds and the orchard was given a severe pruning to prepare it for next year.

and one-fourth per cent oil resulted in a heavy entrance of worms. Arsenate of lead and one per cent oil was used in the next cover followed by arsenate of lead and lime on July 25. This schedule gave an average lead load at harvest of nearly .08 grain per pound of fruit and nearly .035 grain of arsenic.

This arsenic load was reduced to well below the tolerance with three per cent by volume cold hydrochloric acid, but nearly three times the tolerance remained when fruit was put through a brush dry cleaner. The lead load was reduced to the tolerance on all but Grimes with the same treatment. A large number of washing materials, heated solutions, and wetting agents have been tried since 1929.

Removing rough bark on apple trees as an aid in codling moth control.

Orchard Soil Management

The south half of the orchard was seeded down in 1928. Serious results of continual cultivation followed by erosion are still evident in this area. The small block of Winesap in the southeast corner of the orchard has never been cultivated, but has received light annual applications of straw and manure around the trees. All trees have received an annual application of sulphate of ammonia. About one-third of the orchard has been given a light straw mulch each year. The satisfactory size of the fruit in the fall of 1933, following a very dry summer, can be at least partly attributed to this straw mulch practice.

Peach Variety Plots

Winter temperatures have been sufficiently low for the past three winters that no fruit buds survived, even on varieties supposedly hardy to low winter temperatures. Trees have been headed back heavily and are in productive vigor, considering the age of the trees.

Use of Ice in Insulated Cool Air Apple Storage

This project has been completed, and a discussion of results will be found in Purdue Experiment Station Bulletin 379, which is free on request.

Pear Blight and Variety Test Plot

The production of pears has ceased to be profitable in Indiana, because of the high death rate of the trees due to pear blight. About one acre of pear trees has been planted along the west side of the apple orchard. These trees are on blight resistant roots and bodies. At present, the scaffold branches are being budded over to a number of the best varieties of pears.

The Farm Garden

The farm garden as laid out on the Moses-Fell Farm is suggestive of one of the most valuable enterprises on the average Indiana farm. It provides an abundance of high quality vegetables so essential to health and happiness of the whole family throughout the year.

The farm garden laid out on the Moses-Fell Farm is representative of a typical garden. It consists of an acre of ground, half in garden each year, the other half planted to soybeans in preparation for the garden operations the following year. Sufficient plantings of small fruits are included along with the vegetables to meet the family needs.

The farm garden at the Moses-Fell Farm has provided more than a hundred dollars worth of vegetables and strawberries each year for the past three years. Copies of plans and suggested lay-outs for the farm garden may be secured free by writing the Purdue Agricultural Experiment Station, Lafayette, Indiana.

A view of one of the tobacco plots which has produced 1,800 pounds of cured leaf per acre. The continued and increasing interest in this crop makes these experiments of interest to a large group of southern Indiana farmers. Applications of 500 lbs. to 1,000 lbs. per acre of a 3-16-9 fertilizer have proved efficient.

POULTRY

So that it might serve as a demonstration of practices suited to southern Indiana conditions, the flock of 800 Barred Plymouth Rocks is handled (apart from the breeding work) with a view to simplicity and economy.

During the record year ending September 30, 1933, the feed cost of the laying flock (using home mixed feed) was 74 cents per bird, or seven cents per dozen eggs produced. The average investment in laying houses and equipment per bird was $1.34, the depreciation and interest charges on which amounted to nine and one-half cents per bird, or one cent per dozen eggs produced during the year. Despite a low average egg price, the laying flock earned 55 cents per bird, exclusive of labor.

Individual records are kept on each bird by means of trap nests. All of the chickens have leg bands and individual numbers.

The growing flock is also simply housed and cared for. In the fall of 1933, 683 pullets were housed at an average cost of 26 cents apiece exclusive of labor.

To further develop the flock as a source of good breeding stock, 500 pullets are trapnested the year around, and special breeding pens are made up of the best females, as judged by production, egg size and past performance (if any) as breeders.

Of the 2022 chicks hatched during the 1934 season, 399 were pedigreed and wingbanded from the three special breeding pens.

From time to time, in the form of hatching eggs, new blood is introduced from outstanding breeding farms of the country. During the 1934 season 130 such eggs gave 104 chicks (an 80 per cent hatch) to be used in further developing the flock.

The most noticeable improvement in the 1933-34 season over previous years has been the increase in average egg weight. This detail is of growing importance as more and more markets are operating on a "quality" basis in which egg size plays a large part.

The Poultry Department, through Stephen M. Walford, Extension specialist, has supervised the management and breeding work of the flock.

RURAL ELECTRIFICATION STUDIES

The Agricultural Engineering Department, through T. E. Hienton, has cooperated during the year in studying the application of electrical energy to many farms. Chick brooders are operated by electricity as well as spray machinery, grinders, graders, pumps, codling moth traps and household equipment. Data are collected on the comparative costs of these operations.

LIVESTOCK

The livestock work on the farm is carried on to study certain problems that have a bearing on the future development of this industry in southern Indiana. The Department of Animal Husbandry of the Agricultural Experiment Station—Professor F. G. King, Chief, and the Bureau of Animal Industry, U. S. Department of Agriculture cooperate on the sheep and cattle projects. Professor Claude Harper, Asst. Chief of the Department of Animal Husbandry, acts as adviser and supervises the experimental phases of the work.

A group of Delaine Merino ewes and lambs. These sheep are included in the lamb production tests conducted on the farm. The growing interest in sheep production makes this work of particular interest to live stock farmers.

A COMPARISON OF TYPES OF EWES

Three-Year Average 1930-1933

During the past three years, three types of ewes have been used in the sheep production project at the Moses Fell Annex Farm. They would be classed as Merino ewes, Western ewes, and native Lawrence County ewes.

During the three-year period, an average of 19 native Lawrence County ewes, 22 Western ewes and 27 Merino ewes were used. They have been compared with reference to feed costs and lamb and wool production. In the fall of 1929, 25 Western ewes and 25 native Lawrence County ewes were purchased for this project and the Merino ewes that were already on the Moses Fell

Annex Farm were included in the sheep production project. That fall the native Lawrence County ewes cost eight dollars per head and included ewes from two to four years old. The Western ewes cost six dollars per head and were five year old ewes.

All of these different types of ewes were bred to Southdown rams. The same rams and the same ewes were used for a three-year period, Merinos excepted. The same Merino ewes were not used each year but they were all of the same type and breeding and hence, would have little effect upon the results.

Three Southdown rams were used in this project. They were of medium size, of good type and quality. The native Lawrence County ewes that were purchased for this project were considered by a number of people who saw them as representative of the average of Lawrence County ewes with reference to type, quality, and conformation. The Western ewes were of the white-faced type and their breeding was approximately one-half Rambouillet and one-half Lincoln. These ewes were bred in Idaho and were used at the Animal Husbandry Experimental Farm at Lafayette before they were taken to Bedford. The Merino ewes were developed on the Moses Fell Annex Farm and built up from a flock that had been started about 1920.

These ewes were all given the same feeds. However, each group received different amounts of harvested feed according to their thrift and condition. During the grazing season, all ewes and their lambs were together in the same pastures. They were also together in the same pastures during the breeding season. The following table shows the three-year records of harvested feeds used for the various types of ewes.

THREE-YEAR AVERAGE 1929-1933

	Native	Western	Merino
Ration	Oats Shelled corn Corn silage Legume hay	Oats Shelled corn Corn silage Legume hay	Oats Shelled corn Corn silage Legume hay
Number ewes per lot	19	22	57
Total feed consumed:			
whole oats	4,183.3 lbs.	4,813.0 lbs.	9,983.3 lbs.
shelled corn	154.0 lbs.	265.3 lbs.	168.3 lbs.
corn silage	9,375.7 lbs.	10,758.3 lbs.	20,180.0 lbs.
legume hay	4,827.0 lbs.	5,969.3 lbs.	10,184.7 lbs.
Number of days on feed	163	163	161
Average daily feed:			
whole oats	1.353 lbs.	1.345 lbs.	1.086 lbs.
shelled corn	.0498 lbs.	.0741 lbs.	.0183 lbs.
corn silage	3.033 lbs.	3.005 lbs.	2,195 lbs.
legume hay	1.561 lbs.	1.668 lbs.	1.108 lbs.
Cost of feed:			
whole oats	$39.30	$43.08	$91.49
shelled corn	1.25	2.23	1.18
corn silage	20.40	23.17	42.69
legume hay	33.81	39.39	66.47
Total	94.76	107.87	201.83
Average cost per sheep	4.99	4.90	3.54
Average cost per sheep per day	.0307	.0301	.0219

There was a great deal of difference in the pounds of wool sheared by the various groups. The native ewes sheared only 6.3 pounds of wool average per year while the Merino ewes sheared 10.9 pounds per ewe per year and the Western ewes averaged 9.3 pounds of wool.

The percentage of lambs raised to a marketable age from the various types of ewes were as follows: 92 per cent from the native Lawrence County ewes, 130 per cent from the Western ewes and 94 per cent from the Merino

FLEECE WEIGHT OF VARIOUS TYPES OF EWES

	1931			1932			1933			Average		
	Native	Western	Merino	Native	Western	Merino	Native	Western	Merino	Native	Western	Merino
Number ewes sheared	24	24	53	20	23	60	11	20	57	55	67	170
Total pounds wool	160	270	605	117	187	673	70	167	570	347	624	1848
Av. wt. per fleece	6.6	11.2	11.4	5.9	8.1	11.2	6.4	8.3	10.0	6.3	9.3	10.9
Av. price per lb. c	.17	.16	.20	.12	.12	.12	.31	.28	.26	....	....	....
Gross returns per ewe per year for wool	....	....	....	....	....	....	....	....	....	$ 1.27	$ 1.83	$ 2.07

ewes. These percentages are based on the number of lambs marketed in comparison with the number of ewes on hand when the lambing season began.

The average age of the various types of lambs when sold showed the natives to be 7.7 months of age, Westerns 7.7 months of age, and the lambs from the Merino ewes to be 8.4 months of age. It was possible to sell 36 per cent of the lambs from the native ewes at weaning time, 29 per cent of the lambs from the Western ewes and 25 per cent of the lambs from the Merino ewes.

GROSS RETURNS PER EWE PER YEAR

	Native Ewes	Western Ewes	Merino Ewes
Lambs	$3.49	$4.51	$3.40
Wool	1.27	1.83	2.07
Total	4.67	6.34	5.47
Harvested feed costs	4.99	4.90	3.54
Profit or loss	—$0.32	+$1.44	+$1.93

The table presented showing the gross returns per ewe per year is based on the number of ewes on hand at the beginning of the lambing season. This table does not include the cost of fattening lambs after weaning. The low cost of feed for the Merino ewes makes them show advantageously with reference to the profit or loss. On the other hand, the crossbred Merino lambs were marketed at an older age and less of them went to market at weaning time than from the Western ewes. Both the Merino ewes and the Western ewes have made a creditable showing in comparison with the native Lawrence County ewes. The native Lawrence County ewes sheared less wool and returned less income from wool than the other two types. At the same time, the native Lawrence County ewes did not produce any greater returns from lambs than the Merino ewes. It appears that there is an opportunity for improvement in both lamb and wool production in the native Lawrence County ewes.

A COMPARISON OF MERINO LAMBS AND SOUTHDOWN-MERINO CROSSBRED LAMBS

A Three-Year Average 1930-1933

In the fall of 1929, a project was developed at the Moses Fell Annex to secure information relative to comparative gains, market finish and cost of Merino lambs and Southdown-Merino crossbred lambs.

The Merino ewes used in this project were all high grade and from external appearances of conformation and fleece were essentially purebred. Approximately 75 per cent of the wool sheared from these ewes from year to year graded Delaine and about 25 per cent graded half-blood.

The Merino lambs were sired by a purebred Merino ram of smooth type and conformation with an excellent fleece. The get of this ram had produced fleeces that were twice champion Delaine fleeces at the Indiana State Fair. The Southdown rams were purebred, medium-size, of good type and quality.

During the three-year period this project was in progress at the Moses Fell Annex Farm, 81 ewes were bred to a Southdown ram and 96 ewes were bred to a Merino ram. These ewes were fed together throughout the entire year except during the breeding season. The rams were turned with the ewes each year shortly after the middle of September and kept with them until after the middle of November—a period of slightly more than two months.

Five of the Merino ewes in the group bred to a Southdown ram, failed to produce lambs, and ten of the 96 ewes bred to the Merino ram failed to drop lambs. Seventy-seven crossbred Merino lambs were marketed from 81 ewes that were offered for service during this three-year period. Seventy-three Merino lambs were raised to a marketable age. Thus, a 95 per cent crossbred lamb crop was marketed and a 76 per cent Merino lamb crop was produced.

The crossbred lambs were sold at an approximate age of 8.4 months and the Merino lambs went to market when they averaged 9.7 months of age. Twenty-five per cent of the crossbred lambs were sold at weaning time and two per cent of the Merino lambs were sold at weaning time. The crossbred lambs sold for an average of $5.57 per hundred and the Merino lambs brought $5.35 per hundred—a difference of 22 cents per hundred in favor of the crossbred lambs.

It cost $3.54 per year for harvested feed for these Merino ewes. This includes both groups, the ones that produced the crossbred lambs and those that produced the Merino lambs. We do not have the exact cost of fattening the lambs after weaning, but owing to the fact that it was necessary to feed the Merino lambs approximately 40 days longer than the crossbred lambs, in order to get them to a fairly satisfactory market weight and finish, it is obvious that the difference in lower feed cost would be in favor of the crossbred lambs.

These Merino ewes, including both groups, sheared an average of 10.9 pounds of wool per ewe per year which brought an average return of $2.08 per ewe, per year.

All crossbred lambs were marketed at an average weight of 64.4 pounds per lamb at the market. All the Merino lambs were marketed at an average weight of 62.3 pounds per lamb.

The returns per ewe from lambs is secured on the basis of ewes bred for lamb production and includes all ewes that failed to produce lambs.

The returns from wool were the same from each group of ewes. The ewes that produced the crossbred lambs returned $3.41 per ewe from lamb production and $5.49 per ewe, including both lambs and wool. The ewes that produced the Merino lambs returned $2.54 per ewe from lamb production or $4.62 per ewe including both wool and lambs. Thus, the ewes bred to the Southdown rams returned 87 cents more per ewe than those bred to the Merino rams.

The crossbred lambs were more profitable, matured more quickly, and were of more desirable market quality. The crossbred lambs were stronger at birth and started to nurse their mothers more easily than the Merino lambs. It is also interesting to note that the Southdown rams settled more ewes in lamb than the Merino ram and a larger per cent of crossbred lambs were raised to a marketable age.

UNIVERSITY OF ARIZONA LIBRARY

Circular No. 204 June, 1934

THE USE OF RAPID CHEMICAL TESTS ON SOILS AND PLANTS AS AIDS IN DETERMINING FERTILIZER NEEDS

A convenient portable kit containing equipment for rapid soil and plant tests.

UNIVERSITY OF ARIZONA
LIBRARY

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

Rapid chemical tests on soils and plants offer a practical and inexpensive method for determining soil reaction (acidity) and available plant food supply.

The system of testing described in this circular makes use of practically identical reagents, equipment and technique for both soil and plant tests.

The tests on soils indicate the reaction (acidity), the dilute acid soluble phosphorus and the water soluble and replaceable potassium.

The tests used on plant tissues indicates the relative importance of nitrate, phosphate and potassium in relation to other possible limiting factors.

Such tests supply valuable information regarding plant food supplies from which it is possible to make recommendations for the proper use of fertilizers.

As a basis for a definite fertilizer recommendation, the test results should be coupled with the general experience as to amount of fertilizer and time and method of application which has been found profitable.

Since the productiveness of a soil is not solely a matter of a certain number of pounds of plant food per acre, full consideration should be given to other possible limiting factors.

THE USE OF RAPID CHEMICAL TESTS ON SOILS AND PLANTS AS AIDS IN DETERMINING FERTILIZER NEEDS

by

S. F. Thornton, S. D. Conner and R. R. Fraser

For determining soil reaction and supply of available plant nutrients, rapid chemical soil and plant tests have come into extensive use during the past few years. In the hands of competent workers such tests are proving valuable supplements to field plot, greenhouse and laboratory methods already in use. They afford a means of rapid diagnosis, are simple and inexpensive to use and are an aid in determining fertilizer needs for local fields or areas. The proper use of the tests described in this circular make it possible to more accurately determine the fertilizer needs of the various crops on individual farms. The tests can be made by anyone who can distinguish color and who has had proper instruction in their use. While no special scientific training is necessary for making the tests, considerable experience is necessary for their proper interpretation. Continued use of the tests and correlation of test results with crop responses to fertilizer applications under different soil conditions will greatly increase the reliability of interpretations by individual operators.

The potential productiveness of a soil is dependent upon many factors. Among the more important of these are physical condition, water supply, temperature, length of growing season, reaction and supply of available plant food. While soils containing an abundant supply of nitrogen, phosphorus and potassium are not always highly productive, experience has shown that highly productive soils always contain an abundance of these essential plant nutrients. For this reason a knowledge of the nutrient supply of the soil is of great practical importance.

Because the productiveness of a soil is not solely a question of a certain number of pounds of plant food per acre, in the interpretation of results of the tests, full consideration should be given to all other known characteristics of the soil in question. If any one of the physical factors governing plant growth is unfavorable, a close correlation between chemical tests and plant growth is not to be expected. Also it should not be expected that such tests definitely will answer the questions as to exactly how much or precisely what kind of fertilizer will prove most profitable or what will be the yield. The tests do, however, give valuable indications as to plant food supply from which better fertilizer recommendations can be made.

J—Clermont, Avonburg, Cincinnati and Holly silt loams.
K—Fairmont and Switzerland silty clay loams.
L—Lickdale, Johnsburg, Tilsit, Zanesville and Holly silt loams; Muskingum stony loam.
M—Frederick, Bedford, Hagerstown, Guthrie, Lawrence and Huntington silt loams.
N—Bainbridge, Dubois, Haubstadt and Robinson silt loams.
O—Princeton fine sand and fine sandy loam; Logan and Owensville silt loams.
P—Iva, Muren, Pike and Alford silt loams.

The tests described in this circular are, in part, adaptations from the numerous rapid soil tests developed and used during the past few years. They make up a system in which an attempt has been made to bring together good features of the many such tests now in use. Especially desirable is the plan whereby practically identical reagents, equipment and technique are used with both soils and plants. The tests on soils indicate the dilute acid soluble phosphorus and the water soluble and replaceable potassium supply. The tests on plants indicate the nitrate nitrogen, phosphate phosphorus and total potassium content. With soils they indicate the ability of the soil to supply nutrients to the plant and with plants, the relative nutrient level in relation to other possible limiting factors.

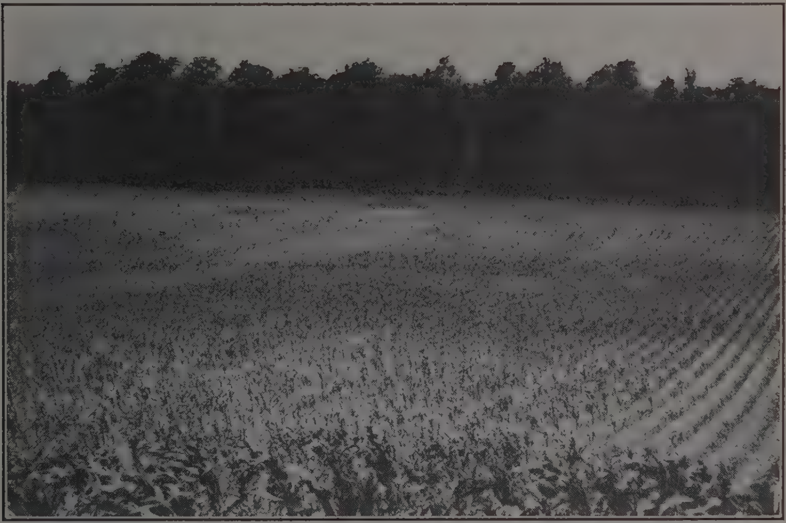

Fig. 3. Often samples from knolls, slopes and low portions of fields and from distinctly different soil types will give entirely different test results.

HOW TO COLLECT REPRESENTATIVE SOIL AND PLANT TISSUE SAMPLES FOR TESTING

Soil Sampling.—Samples may be taken at any time of the year. If a single composite sample is to represent an entire field of an acre or more it should be taken from about 10 places well distributed over the area. Composite samples may be used except that soils from widely different soil classes or types should not be mixed for testing. Often samples from knolls, slopes and low portions of fields and from distinctly different soil types will give entirely different test results. Testing such samples separately may furnish information of much practical value, especially in regard to lime requirements.

Soil augers are suitable for securing soil samples but a spade or trowel is more often used. With a spade or trowel a vertical cut is made to a depth of 6 to 8 inches and a thin slice down the face of this cut taken for the sample.

Any grass or rubbish on the surface should be removed before the sample is taken. The individual samples to be composited should be mixed, all soft clods and lumps broken up, and stones, hard clods and rubbish removed. A half-pint of soil is sufficient to keep for testing. Samples for phosphorus and potassium tests should be air-dried but not dried by means of artificial heat. Moist soils may be used for acidity determinations.

Dust from gravel and limestone roads is known to affect materially the adjacent soil, especially as to reaction and available phosphorus content. This effect often extends 400 feet or more away from the road and should be taken into consideration in sampling. Areas adjacent to such roads should be sampled separately and not composited with other portions of the field. In sampling pasture land and fields where stock have been kept, locations near the entrance where the stock are likely to congregate should be avoided.

Often the testing of subsoil as well as surface soil may be desirable, especially for acidity. In general subsoils in Indiana, as shown by plant growth, tend to be much more deficient in available phosphorus than surface soils. On the average there is no tendency for available potash supply in subsoils to be either higher or lower than that in surface soils. Chemical tests on subsoils tend to show a relatively higher available phosphorus supply than is indicated by plant growth and response. For potassium, plant growth and chemical tests correlate as closely with subsoils as with surface soils.

For each test described in this circular a teaspoonful or less of soil is used. From this sample interpretations are made covering areas containing millions of pounds of soil. This emphasizes the absolute necessity for careful selection of the sample to be used.

Selection of Material for Plant Tissue Test.—The care in sampling already emphasized for soils applies to plants. It is obvious that a single plant may fail to give a true picture of an entire field. A careful survey of the field will show that a majority of the plants are represented by certain types. Plants for testing should be selected from these representative types. The number of plants necessary to secure a representative test will vary with the uniformity and size of the field. Often six or eight plants will suffice but a larger number should be taken whenever this seems desirable. Samples from these several plants may be composited and a single test made.

Different parts of plants give different results and certain parts have been found to give more reliable indications of fertilizer needs than others. For nitrogen, main stems and leaf petioles have been found satisfactory. In general, tests for phosphorus should be made on main stems or leaf petioles from actively growing portions of the plant. For potassium, with grasses and cereals, tests should be made on the base of the leaf near the middle of the stem and for other plants the main stems or leaf petioles. The following list of some of the more common farm crops shows the parts of the plants upon which the tests should be made:

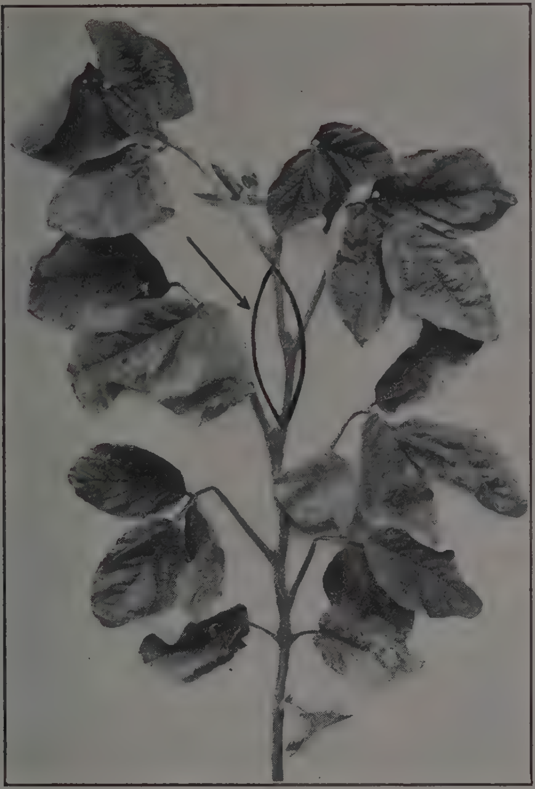

Fig. 4. With the soybean plant, the upper part of the main stem is used for both phosphorus and potassium tests.

Corn—

Nitrogen—Base of main stalk.

Phosphorus—Growing tip of main stalk or main stalk just below tassel.

Potassium—Base of leaf at ear node.

Wheat, oats, barley, rye—

Nitrogen—Main stem.

Phosphorus—Growing tip of main stem.

Potassium—Base of leaf near middle main stem.

Potatoes—

Nitrogen—Main stem near ground.

Phosphorus—Main stem near ground.

Potassium—Main stem near ground.

Alfalfa, clover, soybeans—

Nitrogen—Normally no nitrate nitrogen is present.

Phosphorus—Growing tip of main stem.

Potassium—Main stem.

Tobacco—

Nitrogen—Base of midrib of leaf from upper main stem.
Phosphorus—Base of midrib of leaf from upper main stem.
Potassium—Base of midrib of leaf from upper main stem.

Sugar beet, spinach, turnips—

Nitrogen—Leaf petiole.
Phosphorus—Leaf petiole.
Potassium—Leaf petiole.

Tomato—

Nitrogen—Leaf petiole from middle of main stem.
Phosphorus—Leaf petiole from middle of main stem.
Potassium—Leaf petiole from middle of main stem.

PREPARING TEST REAGENTS

Reaction (Soil Acidity)

Indicator No. 1. Dissolve 0.04 grams of brom-thymol blue powder in 5 cc of 95% ethyl alcohol, add 95 cc of distilled water and make to pH 6.6 (yellowish-green color) by adding, drop by drop, a 0.2 normal solution of sodium hydroxide. The pH range is 5.8 to 7.5.

Indicator No. 2. Prepare a solution of brom-creosol green as for Indicator No. 1 and adjust to pH 4.6 (yellowish-green color). The pH range is 3.8 to 5.5.

Nitrate (Plants)

Reagent No. 1. Dissolve 1 gram of diphenylamine in 100 cc of concentrated sulphuric acid. This solution is very corrosive.

Phosphate (Soils and Plants)

Reagent No. 1. Dissolve 4 grams of ammonium molybdate in 500 cc of distilled water and add, slowly and with constant stirring, a mixture of 63 cc of concentrated hydrochloric acid and 437 cc of distilled water. As this solution may become unsuited for use after standing for a few months, it is desirable to prepare a solution of five times this concentration and to dilute as needed.

Reagent No. 2. Dry powdered stannous chloride or stannous oxalate.

Potassium (Soils and Plants)

Reagent No. 1. Dissolve 5 grams of sodium cobaltinitrite and 30 grams of sodium nitrite in distilled water, add 5 cc of glacial acetic acid, make to 100 cc volume and allow to stand for several days. Add 5 cc of this solution to a solution of 15 grams of sodium nitrite in 100 cc of distilled water and adjust to pH 5.0 with acetic acid.

Reagent No. 2. Isopropyl alcohol (anhydrous).

Reagent No. 3. Ethyl alcohol (95%). When ethyl alcohol for use as a reagent is difficult to obtain, a mixture of 60 parts anhydrous methyl alcohol, 40 parts anhydrous isopropyl alcohol and 5 parts of distilled water may be substituted. Completely denatured alcohol is not satisfactory.

Soil Reaction (Acidity)

Soils, according to reaction, may be classified as acid (sour), neutral and alkaline (sweet). Not only do most cultivated plants have a definite soil reaction preference but soil reaction may exert a very powerful influence upon plant nutrient availability and upon fertilizer efficiency. Strongly acid or strongly alkaline soils may contain substances toxic to plants, resulting in poor plant growth regardless of other conditions. While some plants prefer an acid soil, some a neutral soil and some an alkaline soil, the majority of crop plants do best under neutral or slightly acid conditions. This also appears to be the condition favorable to the maximum availability of plant nutrients and the maximum efficiency of fertilizers.

The reaction of a soil may be expressed conveniently in terms of pH, this being merely a numerical expression of the hydrogen ion concentration. The neutral point is pH 7, with higher values indicating increasing alkalinity and lower values increasing acidity. Thus pH 7 indicates a neutral soil; pH 7 to 8 a slightly alkaline soil; pH 8 to 9 a very alkaline soil; pH 6 to 7 a slightly acid soil; pH 5 to 6 a medium acid soil and pH 4 to 5 a very acid soil. Soils more acid than pH 4 or more alkaline than pH 9 are usually not suitable for crop production.

In humid regions, such as Indiana, soils are often acid in reaction, due to the fact that soluble calcium, magnesium and other bases of the original soil material have been leached out of the upper layer of the soil by rain water. In semi-arid and arid regions, on the other hand, leaching is reduced to a minimum and soils are usually neutral or alkaline. In southern Indiana, where the older soils are found, the leached or acid layer of soil varies in depth from 8 to 12 feet; in central Indiana it is approximately 5 feet in depth; and in northern Indiana, 2 to 3 feet.

The majority of Indiana soils are in the range comprising slight to medium acidity, pH 5 to 7. Light colored upland soils tend to be more acid in the immediate subsoil than in the surface soil. It is estimated that three-fourths of Indiana soils are more or less in need of liming, hence a test for soil reaction is very important. Even on slightly acid soil, liming may be profitable for such crops as alfalfa and sweet clover. On moderately acid soils all clovers need lime and on very acid soils even grain crops and grasses require an application of lime for good growth.

Soils of different types respond differently to applications of lime. Soils high in organic matter need lime less than do clay soils of the same pH and clay soils, less than light sandy soils. However, when soils high in organic matter are so acid that they do need liming, a relatively large application is required to correct the acidity. Lime and fertilizer or manure play distinctly different roles and it should be remembered that while either one alone may be of some value, neither can be substituted for the other. If a soil is too acid it should be limed, if it is deficient in available nitrogen, phosphorus or potash, fertilizer or manure should be used to correct such deficiencies.

Test for Reaction of Soils.—Crease lengthwise a strip of waxed paper, add an amount of soil about equal in volume to a grain of corn and add Indicator No. 1 sufficient to slightly more than saturate the soil. Work the indicator back and forth through the soil, making sure of thorough contact. When the reaction is complete drain the excess liquid toward one end by tilting the paper and note the color. If the liquid is colorless or so cloudy that the color is obscured, add a few more drops of indicator and rework through the soil. A distinct blue color indicates a pH of 7.4 or above; a bluish-green, 7.0; a yellowish-green, 6.6; a greenish-yellow, 6.2; and a bright yellow, 5.8 or below.

If a bright yellow color is obtained with Indicator No. 1, repeat the procedure on a second portion of soil using Indicator No. 2. With Indicator No. 2 a distinct blue color indicates a pH of 5.4 or above; a bluish-green, 5.0; a yellowish-green, 4.6; a greenish-yellow, 4.2; and a bright yellow, 3.8 or less.

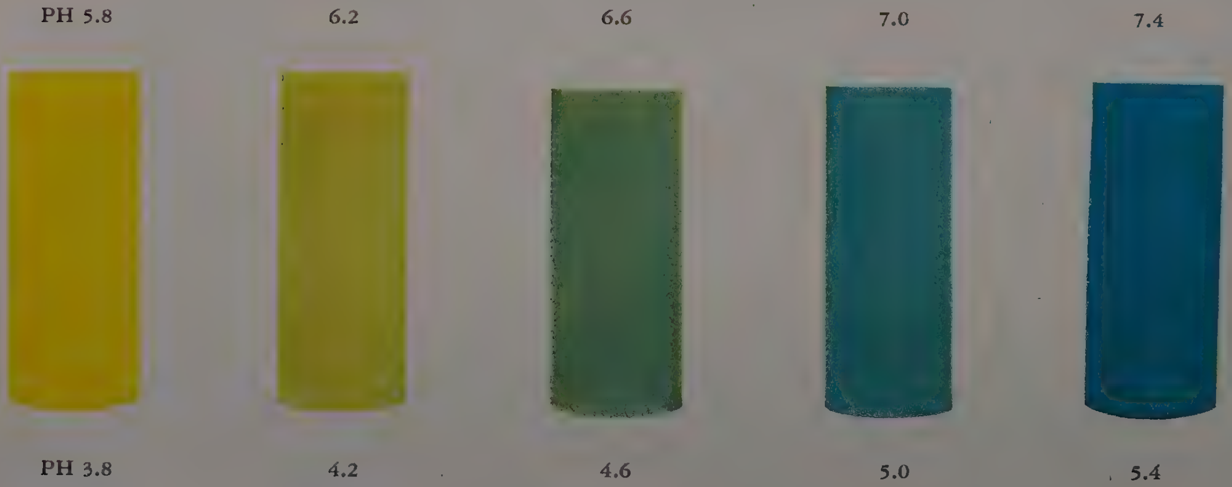
For special purposes other indicator solutions may be desirable. For example, the pH range between 5.0 and 6.0 may be more accurately covered with a chlorphenol red solution prepared as for the above indicators or a double indicator solution may be prepared to cover, roughly, the entire range between pH 4.0 and 8.0.

Nitrogen

Nitrogen in the soil is found chiefly in the organic matter. By the action of soil microorganisms such organic nitrogen is changed into inorganic nitrates, in which form it is readily taken up by plants. A test for nitrate nitrogen often is used as an indication of the available nitrogen supply in the soil. However, the production of nitrates in the soil is so greatly dependent upon physical factors such as temperature, moisture supply and kind of crop that it fluctuates to such an extent during the growing season that such a test is of little value as an indicator of nitrogen needs. Knowledge of the total nitrogen supply probably is of greater value. Color of the soil may be used as a fairly reliable indicator of total nitrogen supply, dark colored soils usually having a relatively high total nitrogen content and light colored soils, a relatively low content. Strongly acid soils tend to be deficient in available nitrogen supply even though the total nitrogen content may be relatively high.

ACIDITY TEST CHART

INDICATOR No. 1 BROM THYMOL BLUE



INDICATOR No. 2 BROM CRESOL GREEN

Nitrogen, which is required by all plants in relatively large amounts, is taken up from the soil principally in the form of nitrates. When the available nitrogen supply is abundant, nitrates accumulate in the conducting tissues of most plants. When the available nitrogen supply is inadequate, or just adequate, nitrates do not accumulate but are utilized immediately in the formation of organic plant substances, especially proteins. Even with soils usually well supplied with nitrogen, there may be periods during the growing season when conditions are unfavorable for nitrification and the nitrate supply becomes inadequate. Leaf color is usually a good index of the adequacy of the available nitrogen supply. With an adequate supply the leaves remain a normal dark green. When the supply becomes deficient, the leaf color changes to a pale yellowish green and there is often a marked tendency toward a reddish purple tinge of stems and branches. The test for nitrates may be used to confirm these external indications of nitrogen supply. Legumes and woody plants, however, do not normally accumulate nitrates in the above ground portions. With such plants the nitrate test cannot be used.

Test for Nitrates in Plants.—With large stemmed plants, split open several stalks or leaf petioles and with smaller plants cut thin discs from stems or petioles and place on a strip of waxed paper or in a glass vial. Add a few drops of the nitrate reagent and note the color produced.

A dark blue color indicates an abundant or excessive nitrogen supply; a pale blue or green color, an adequate supply; and no color accompanied by a pale green color of foliage, a deficient supply.

Phosphorus

Phosphorus has long been recognized as one of the outstanding plant food needs in practically all types of crop production. In Indiana soils, phosphorus deficiency is especially common and responses to phosphate applications are correspondingly large. However, there are Indiana soils which show no profitable responses to applications of phosphate fertilizers.

Phosphorus exists in the soil in many different forms, varying widely in their solubilities. While it is probably true that no one form is utilized by plants to the exclusion of all others, it is generally agreed that extraction with a dilute acid solvent gives a good measure of the phosphorus readily available to plants.

Phosphorus is absorbed from the soil by plants chiefly in the inorganic or phosphate form. Within the plant much of that taken up is changed rapidly into the organic form and is utilized to build up plant tissues. Plants well supplied with available phosphorus do not utilize this element as rapidly as it is taken up but tend to accumulate inorganic phosphates in the conducting tissues. However, plants growing under conditions of a deficient supply of available phosphorus show no such accumulation but convert the phosphorus into organic forms as rapidly as it is taken up.

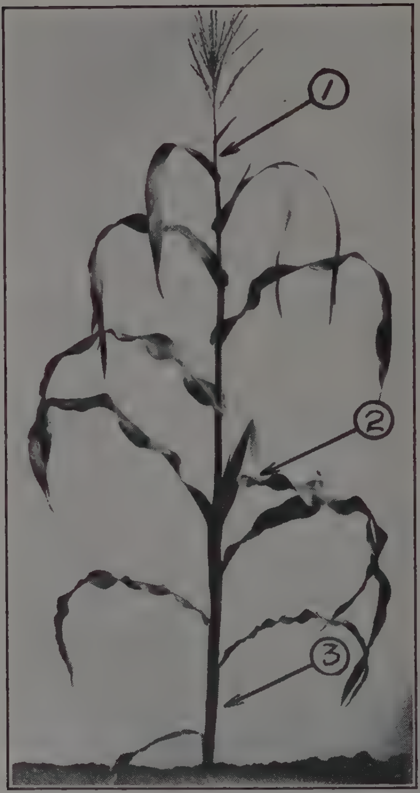


Fig. 5. With the corn plant use

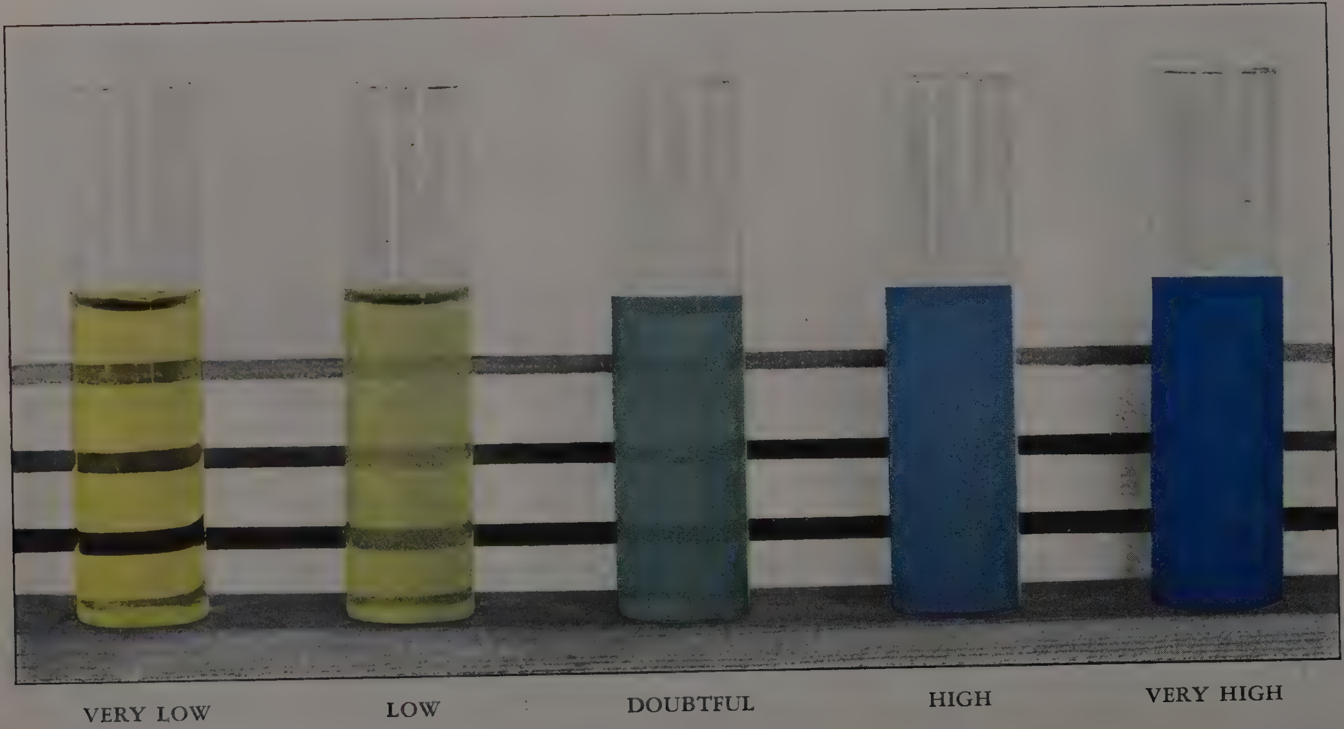
1. For phosphate test—main stalk just below tassel.
2. For potassium test—base of leaf at ear node.
3. For nitrate test—base of main stalk.

As judged by external appearance of the plant, phosphorus deficiency is more difficult to recognize than are other nutrient deficiencies. In external appearance, internal structure and composition phosphorus and nitrogen deficient plants have many characteristics in common. However, while both show a similar restriction in growth, nitrogen deficient plants often develop reddish-purple stems and pale yellowish-green foliage while phosphorus deficient plants often have bluish-purple stems and darker green foliage. Low nitrogen plants contain no nitrate nitrogen but often considerable phosphate phosphorus while low phosphorus plants may contain an abundance of nitrate nitrogen but only a trace of phosphate phosphorus. Thus a test for phosphate in the conducting tissues of the plant gives a dependable diagnosis of phosphorus needs.

Since arsenic gives the same color reaction as phosphorus, the test cannot be used with either soils or plants where spray materials containing arsenic have been applied.

PHOSPHATE TEST CHART



VERY LOW
LOW
DOUBTFUL
HIGH
VERY HIGH

Test for Phosphorus in Soils.—Place 10 cc of Phosphate Reagent No. 1 in a glass vial, add ½ teaspoon level full of soil, shake vigorously for one minute, filter into another vial, add an amount of Phosphate Reagent No. 2 approximately equal in size to a mustard seed and mix. At once observe the color produced, holding the vial between the operator and a source of light. Again add Phosphate Reagent No. 2 to make certain that sufficient has been used. With mucks, greenhouse soils and other soils high in organic matter, add 2 or 3 cc of Phosphate Reagent No. 1 to the filtrate before adding Phosphate Reagent No. 2.

A dark blue color indicates an abundant phosphorus supply; a medium blue an adequate supply; a light blue, a doubtful supply; a green or bluish-green color, a moderately deficient supply; and no color or a yellow color, a very deficient supply.

On alkaline soils the test appears to give less reliable indications of phosphorus needs. Such soils usually give high tests.

Test for Phosphorus in Plants.—Place 1 teaspoon level full of finely cut stems or leaf petioles in a glass vial, add 10 cc of Phosphate Reagent No. 1, shake vigorously for 1 minute, add an amount of Phosphate Reagent No. 2 approximately equal in size to a mustard seed and mix. At once observe the color produced, holding the vial between the operator and the source of light. Add another portion of Phosphate Reagent No. 2 to make certain that sufficient has been used.

A dark blue color indicates an abundant phosphorus supply; a medium blue, an adequate supply; a light blue, a doubtful supply; a green or bluish-green, a moderately deficient supply; and a colorless or yellow, a very deficient supply.

For grain crops, plants upon which seed are fully developed are not suitable for testing. Such plants mature with seed formation and give low tests except under conditions of very high phosphorus supply. Plants, such as the tomato, which fruit more or less continuously, may be tested at any time during active growth.

Temporary standards corresponding to the above interpretations for either soils or plants may be prepared by using varying amounts of di-calcium phosphate and making the test as described for plants, with the phosphate solution replacing the plant material. Tests corresponding to very deficient, moderately deficient, doubtful and adequate are obtained with the use of 0.1 cc, 0.2 cc, 0.6 cc, and 1.5 cc, respectively, of a solution of 0.02 grams of di-calcium phosphate dissolved in 100 cc of approximately 0.75 normal hydrochloric acid.

Potassium

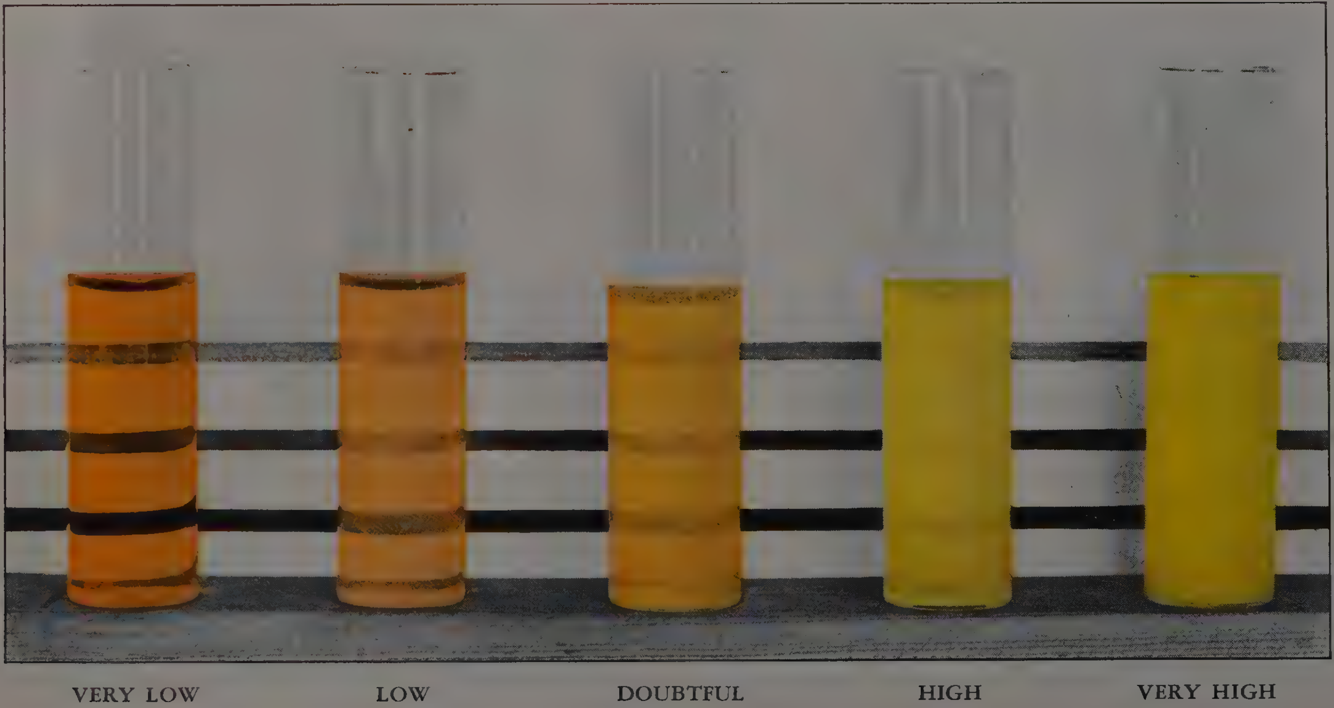
Almost all soils, with the exception of sands, mucks and peats, contain large amounts of total potassium. However, experience has shown that only a very small part of the total potassium in soils is available to plants. Long continued cropping almost always has reduced the available supply to the point where it is no longer sufficient for the needs of crops. Recent developments indicate that even with the soils of the middle western states we are approaching a soil condition where potassium deficiency is the common rule. Many of our soils, which only a few years ago were thought to be abundantly supplied with available potassium, are now showing marked responses to additions of this plant food.

It is quite generally agreed that the readily available potassium in soils exists largely in the replaceable form. Only a small part of the total potassium is found in the replaceable state at any one time. As the replaceable potassium is removed by cropping or by leaching it must be continually resupplied either from the potash containing minerals of the soil or as added fertilizers or manures. Both the amount of replaceable potassium in the soil and the rate at which it can be supplied from the less soluble compounds of the soil are important factors in determining potassium needs. Since subsoils may be well supplied with available potassium, factors which influence root development and extension are often of much importance in determining the ability of plants to secure a supply of potassium sufficient for their needs. If a subsoil is so tight, so poorly drained, or so acid that plant roots do not penetrate into it, the entire potassium supply must be obtained from the surface soil. Under such conditions the surface soil is rapidly exhausted of its supply of available potassium and symptoms of potassium deficiency appear. On soils of the same available potassium content, plants with shallow and restricted root systems may suffer from potassium deficiency much more than do plants with deep and extensive root systems.

Potassium is required by all plants in relatively large amounts throughout the entire growing period. That taken up by young plants may be translocated and utilized by newly developing tissue. Nearly all of the potassium in plant tissue remains in the readily soluble state and is believed to exist in the plant cell almost entirely in the inorganic form. Because of the relatively large amount of potassium necessary for plant growth, depletion of the available supply in the soil by cropping may be rapid. This is especially true if leaves and stems as well as grain and fruit are removed from the land.

As contrasted with the undersized but completely developed plants associated with nitrogen and phosphorus deficiencies, potassium deficient plants often develop normally at first but fail prematurely without normal seed formation. The effect of potassium deficiency upon external appearance varies greatly with different plants but is nearly always associated with mottling, spotting, streaking or curling of the leaves, especially between the veins and along the margins.

POTASH TEST CHART



VERY LOW
LOW
DOUBTFUL
HIGH
VERY HIGH

The potassium concentration in plant sap varies greatly and may be used as a reliable indicator of the available supply to which the plant has access.

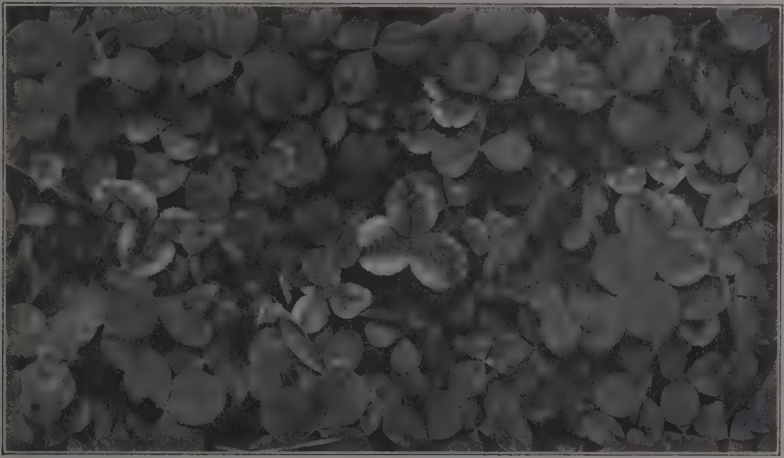


Fig. 6. Potash starved clover plants showing pattern-like spotting of the leaves.

Test for Potassium in Soils.—Place 10 cc of Potash Reagent No. 1 in a glass vial, add 1 teaspoon level full of air dried soil (½ teaspoonful for mucks and greenhouse soils), shake vigorously for 1 minute, filter into another vial until the filtrate amounts to 5 cc, carefully add 2½ cc of Potash Reagent No. 2 and mix. After standing 3 minutes note the amount of precipitate formed, placing the vial against a non-transparent background.

No precipitate or only a trace indicates a very deficient potassium supply; a light precipitate, a moderately deficient supply; a medium precipitate, a doubtful supply; and a dense precipitate, an adequate or abundant supply.

Test for Potassium in Plants.—Place ½ teaspoon level full of finely cut plant material in a glass vial, add 10 cc of Potash Reagent No. 1, shake vigorously for 1 minute, carefully add 5 cc of Potash Reagent No. 3 and mix. After 3 minutes note the amount of precipitate formed, placing the vial against a non-transparent background.

No precipitate or only a trace indicates a very deficient potassium supply; a light precipitate, a moderately deficient supply; a medium precipitate, a doubtful supply; and a dense precipitate, an adequate or abundant supply.

Temporary standards corresponding to the above interpretations for either soils or plants may be made by using varying amounts of potassium chloride and making the test as described for plants with the potassium chloride replacing the plant material. Tests corresponding to very deficient, moderately deficient, doubtful, and adequate or abundant are obtained with the use of

0.2 cc, 0.4 cc, 0.6 cc and 1.0 cc, respectively, of a solution of 1.0 gram of potassium chloride dissolved in 100 cc of a 15% sodium nitrite solution.

Limitations and Interpretations

Some limitations in the application of the tests have already been indicated. The following points are deserving of especial emphasis:

1. Results are only semiquantitative.
2. The soil tests give no information regarding the effect of important physical factors such as water supply, drainage, system of cultivation, temperature and seasonal variations.
3. Soil tests are designed to indicate the capacity of a soil to supply available phosphorus and potassium.
4. Plant tests show the relative nutrient supply as compared to other possible limiting factors. The results apply only to the conditions under which the plants have grown. Thus a nutrient supply which is shown as adequate under conditions where some other factor is limiting may become inadequate upon removal of this other limiting factor.
5. A coordinated system of testing that gives a rather complete picture of the nutrient status of both soil and plant is much more valuable than a single test for any one nutrient.

It should be evident that no general interpretation of test results, applicable to all crops, at all yield levels and for all soil and climatic conditions is possible. In practical interpretations, full consideration should be given to other plant growth factors. The appearance of the plant is often of much assistance. Certainly soil type, water supply and other physical factors which influence fertilizer efficiency and potential productivity must be considered.

The tests serve as good indicators of the type of fertilizer that can be profitably used, that is, whether it should be high in nitrogen, phosphorus or potassium or in some combination of these nutrients. For a definite recommendation these findings should be coupled with the general knowledge as to amount of fertilizer and time and method of application which has been found profitable for different crops and soils. For this reason it is desirable to make use of field plot and greenhouse tests wherever possible. Long continued field plot tests are especially valuable in showing the cumulative effects of fertilizer and other treatments under the various natural conditions that influence the yields of crops.

In general, with the soil and plant tests described in this circular, very low results for any nutrient indicate a definite need for all crops under practically all conditions and very high tests, an adequate supply. Intermediate tests may not be so easily and so definitely interpreted. Except in extreme cases, no crop production factor should be considered alone but only in its relation to other factors.

UNIVERSITY OF ARIZONA

Circular No. 205 October, 1934

INSPECTION OF AGRICULTURAL SEEDS

It pays to sow clean red clover seed of good quality.

OF ARIZONA
LIBRARY

Agricultural Experiment Station
Purdue University
Lafayette, Indiana

This circular contains a report of the agricultural seed inspection for the year ending June 30, 1934. The complete analyses of 1,139 official seed samples are given with full particulars. In addition 344 official samples drawn for test at the request of dealers and 2,447 free test samples of seed were tested during the year.

In accordance with the ruling of the State Seed Commissioner, wholesale seedsmen are required to attach at least one state label to each package of seed delivered to the retail seedsmen, who are then required to attach sufficient additional labels to cover the net weight of the package.

Since it is impossible to test all seed promptly during the rush season, directions are given for making germination tests at home.

Shipments or lots of seed not tagged or seriously misbranded were withdrawn from sale until dealers labeled such seed correctly.

Proper use of this publication will enable purchasers to discriminate between seedsmen who handle good seed and those who handle poor seed. Before buying seed farmers are urged to examine Table 7, the standing of seed distributors, and Table 8, the results of tests on 1,139 official samples.

INSPECTION OF AGRICULTURAL SEEDS

H. R. KRAYBILL, *State Seed Commissioner*
P. B. CURTIS, *Associate Chemist*

O. S. ROBERTS, Chief Inspector. REGINA B. SCHULTE,* Seed Analyst.
Assistant Seed Analysts: PAULINE BALBACH, MARY E. GREY.
Inspectors: C. M. COHEE, J. W. JACKMAN.

The Indiana Seed Law passed in 1921 is essentially a correct labeling law. Poor seed as well as good seed may be sold under the law provided it is correctly labeled. In order that the necessary information may be available the law requires that the seed be labeled with official Indiana State Labels showing minimum percentages of purity and germination and the maximum number of each of the noxious weed seeds per pound. The date of germination test and state or foreign country where the seed was grown must also be stated. This seed law offers an inducement to farmers to grow better seed and also encourages the seedsmen to sell the better grades of seed. Copies of the Indiana Seed Law may be secured by making application to the State Seed Commissioner.

This circular contains detailed results of the inspection of agricultural seeds for the period from July 1, 1933, to June 30, 1934. The inspectors secured from the seed dealers and consumers in all sections of the state 1,483 official samples of seed. Complete analyses of these samples were made and reports were sent to the distributors, dealers and consumers. In addition 2,447 free test samples and 28 Custom House samples were analyzed. The testing of these samples entailed the making of 2,891 purity tests, 14,200 germination tests, 54 examinations and 72 identifications.

Responsibilities of the Wholesale Seedsman

The wholesale seedsman is required to attach at least one Indiana State Label to each package of seed delivered to the retail seedsman. However, if the seed is shipped directly to the consumer it must be tagged to full weight with Indiana State labels.

Responsibilities of the Retail Seedsman

The retail seedsman is required to attach sufficient state labels properly filled out to each package of seed to cover the total weight of the seed before the seed is offered or exposed for sale. These labels can be chosen of such denominations of weight so that they may be removed and attached to a portion of the seed which may be sold from the original package. It should be remembered that every package of seed of one pound or more when sold for seeding purposes must have attached to it sufficient state labels properly filled out to cover the total weight of the package. It should also be remembered that it is just as much a violation of the state law to offer or expose seed for sale for seeding purposes without tagging to full weight as it is to sell the same without tagging.

Responsibilities of the Purchaser

The purchaser should examine the official label carefully before purchasing seed and ascertain whether the seed is of the quality desired. He should insist that all seed which he purchases be tagged properly with official state labels. Attention should be paid to the date of germination on the seed tag. If the germination test was made more than six months before, in many cases it will be well to insist upon a more recent germination test. Table 7 gives the standing of the distributors as determined by the 1934 inspection while

---

* Assistant Botanist, in cooperation with the Division of Seed Investigations, Bureau of Plant Industry, U. S. D. A.

Table 8 shows the results of the analyses of 1,139 official samples. A study of these tables will be helpful to those who purchase agricultural seeds. The farmer should make it a rule to buy his seeds from a reliable dealer, remembering that poor seeds are dear at any price and that quality and not price should be the chief consideration.

Farmers' Exemption

A farmer is exempt from the provisions of the seed law when the seed is grown, sold and delivered by that farmer on his own premises to the purchaser himself. If, however, the seed is advertised for sale by the public press, circular or catalogue, or if the seed is delivered by a common carrier, the farmer is considered as a vendor and must comply with the provisions of the act. Seed taken to community sales for sale must be labeled in accordance with the law.

Free Testing of Seeds

During the past year 2,447 samples of seed were tested free of charge for farmers and seedsmen. The privilege of having these tests made is one of much value to the farmer and the smaller seed dealers who do not have facilities for testing seeds. Not all of the tests requested can be made promptly during the busy season from January to March. For that reason it is important that all samples be sent in as early as possible, preferably from September to December.

Satisfactory tests may be made of the larger field seeds at home, leaving the laboratory facilities of the Agricultural Experiment Station available for the grasses and clovers which are more difficult to analyze.

Directions for Making Germination Tests at Home

The seed to be germinated should be mixed thoroughly and the required number of seeds (100 seeds of grains and 200 of clovers and other small seeds) counted out just as they come.

The plate germinator is satisfactory and very simple to operate. The seeds to be germinated are placed between two thicknesses of folded blotting paper or cloth (heavy grade of muslin or canton flannel). This should be moistened and placed between ordinary tin or porcelain plates and kept in a warm room where the range in temperature is from approximately 85 degrees during the day to 65 degrees at night. The place selected for the test should not be too near a window, stove or register.

The time required for germination tests varies with different kinds of seed. Under favorable conditions grass and clover seeds begin to sprout in three or four days. The tests should be continued for ten days or two weeks. Every two days the tests should be examined and a record made of the number of seeds that have sprouted. Also the blotting paper or cloth must be kept sufficiently moist. The number of seeds which germinate out of the 100 seeds will give the percentage of germination.

If a sample of seed for test is to be sent to the seed laboratory the following directions for securing the sample should be observed.

Directions for Taking of Samples

1. The minimum weight of seed forwarded for test should be approximately:
    - (a) Two ounces (cupful) of grass seed of any kind or of white and alsike clover;
    - (b) Five ounces (cupful) of red and crimson clover, alfalfa, millet, flax or seed of like size;
    - (c) One pound (pint) of cereals or seed of like size.
2. Samples may be drawn:
    - (a) With seed triers;
    - (b) With long stickers;
    - (c) By hand, taking approximately equal parts of the sample from at least three different places in the sack, including the top and opposite sides as near the bottom as practicable.

3. Samples should be drawn from each bag when there are not more than five bags in the lot, from every fifth bag when there are more than five bags, but never from less than five bags. All samples so drawn are combined into one composite sample.

Tolerance

Under the most perfect and approved conditions of testing seeds, variations will occur in purity and germination tests. For this reason the Association of Official Seed Analysts has adopted tolerances or allowances for purity and germination tests. Samples of seed with a guarantee within the tolerances are not considered to be seriously misbranded under the provisions of the Indiana Seed Law, but seed dealers will be expected to change the guarantee on the unsold portion to correspond to the analysis found by the Seed Commissioner.

Table of Tolerances for Germination Tests

Percentage of Germination	Percentage of Allowable Variation
90 or over	6
80 or over and less than 90	7
70 or over and less than 80	8
60 or over and less than 70	9
50 or over and less than 60	10
40 or over and less than 50	10
30 or over and less than 40	9
20 or over and less than 30	8
10 or over and less than 20	7
0 or over and less than 10	6

Tolerance for Purity Test

In determining the tolerance for purity the sample shall be considered as being made up of two parts: (1) pure seed and (2) everything not pure seed. The tolerance allowed shall be two-tenths of 1 per cent plus 20 per cent of the lesser part. Example: Seed marked 98 per cent pure, the lesser part is 100 minus 98, or 2. Twenty per cent of 2 equals 0.4. Therefore, the tolerance allowed would be 0.2 plus 0.4, or 0.6.

Violations of the Law

It is a violation of the State Seed Law to offer, expose for sale or sell misbranded seed or seed not tagged to full weight with official labels. During the past year nine cases of misbranding and five cases of non-tagging were called to the attention of prosecuting attorneys. Of the fourteen cases ten resulted in convictions while four of them have not been reported by the prosecuting attorneys to date.

Filling Out Official Label

Purity

The minimum purity means the percentage of pure seed of the kind and variety given on the official label. Statements of purity, as 97 per cent including 2 per cent crop seeds, or 95 per cent and 2 per cent crop seeds, will not be permitted. In cases where the seed contains two or more kinds of agricultural seed, each present in excess of 5 per cent, the seed mixture should be labeled with the official green colored mixture labels, Style C.

The filling out of the column "per cent of seed" on the mixture labels can be explained best by an example. For instance if a mixture is composed of 60 per cent Kentucky Blue Grass with a purity of 80 per cent and 40 per cent of

Red Top with a purity of 90 per cent, the per cent of Blue Grass should be given as 48 per cent, obtained by taking 80 per cent of 60. The Red Top should be given as 36 per cent, obtained by taking 90 per cent of 40.

The percentage of purity on the large seeds such as soy beans, corn, wheat, vegetable seeds, etc., must be given on the official label the same as on any other seed.

Germination

The term minimum germination means the percentage of sprouts obtained in the prescribed time for the test. If the seed contains hard seeds this percentage should be stated after the term "hard seed" on the official label. In no case should the sum of the percentages of sprouts and hard seeds be given as the percentage of minimum germination.

Distributors should not ship seed until the germination test is completed. The statement "In Test" on the official label does not meet the provisions of the seed law. If there is a demand for the seed the dealer may be tempted to sell the seed before he receives a report on the germination, thus placing himself liable to prosecution.

Noxious Weed Seeds

The number per pound of each of the noxious weed seeds present must be listed on the reverse side of the tag irrespective of the number present. The term "trace" is not permissible. The statement of the noxious weed seeds in terms of per cent or in terms of proportion will not be permitted.

Place Where Grown

The official tag must give the name of the state, territory or foreign country where the seed was grown. Terms such as Domestic, U. S. A., Northwestern, and Central States do not meet the requirements of the law, and seed found so labeled will be immediately removed from sale until the tags have been corrected.

Certified, Verified and Affidavit Seed

Certified seed is seed whose purity, germination, and variety is certified to by some state certifying agency or an agency closely associated with some state office or department. The seed is shipped in sealed sacks with a certified seed tag attached. During the growing season the fields are inspected to ascertain trueness to variety of crop, and after the harvest the seed is tested to determine whether it meets the prescribed standards of the certifying agency. In Indiana the Indiana Corn Growers' Association certifies corn, wheat, oats, lespedeza, and soy beans. The other most commonly certified seed found in the state is Grimm alfalfa.

Verified-Origin seed is seed whose origin is attested to by certain government approved seed dealers. Seed verification service deals with origin only, meaning Place Where Grown, and gives no guarantee as to the variety, purity or viability of the seed. At the present time red clover and alfalfa are the only seeds verified as to origin. Verified seed is tagged with tags bearing the official verification emblem.

Affidavit Grimm is alfalfa seed for which the grower has made affidavit as to its being Grimm alfalfa. This affadivit seed is not regulated by either State or Federal Government.

Attention Distributors and Dealers

If seeds such as oats and soy beans are sold for seeding purposes they come under the provisions of the law and must be tagged with Indiana seed tags. It is not proper for the dealer to say that he is selling his oats or soy beans as feed oats or feed soy beans and thereby attempt to evade the seed law when these seeds are actually being sold for seeding purposes. The mere fact that the dealer says that he is selling his oats and soy beans as feed when it is generally known and he himself as well knows that they are going to be used for seed does not in any way relieve him from the responsibility of complying with the seed law by properly tagging the oats and soy beans with Official Indiana seed tags.

Summary of 1934 Inspection

A majority of the samples examined during 1934 met their guarantee very closely. Table 1 shows that there has been a continued marked improvement in the correct labeling of seeds in the last few years. In fact the per cent of samples seriously misbranded in 1934, namely 14.0, was the lowest since the seed law was enacted in 1921.

Tables 2 and 3 give the average analysis of samples in the 1922 and 1933 seed inspections. Examination of Table 4 shows clearly that the quality of much of the seed could be improved by more thorough cleaning. Tables 5 and 6 show the percentages of official samples of red clover, alfalfa, sweet clover, alsike clover and timothy which contained some of the various noxious weed seeds.

Circular No. 206 October, 1934

PLANT FORCING WITH ELECTRIC LIGHTS

The lowest wattage lamps produce sufficient light for the practical forcing of many greenhouse flowering crops.

UNIVERSITY OF ARIZONA LIBRARY

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

The following pages contain specific information regarding equipment and cultural suggestions for the grower who wishes to use artificial light as a method of greenhouse forcing. The suggestions are based on the results of investigations at various institutions over a period of several years.

The results of the investigations on the practical application of artificial light during the night to the forcing of various greenhouse crops show that many plants respond to relatively low light intensities as produced by 15- to 40-watt Mazda lamps. One lamp may be used to light as much as 30 square feet of bench space. The lights need to be applied for from four to six hours each night. They may be used at any time during the night convenient to the grower.

Greenhouse crops fall into three general groups: (1) those which fail to produce marked results of commercial value, as rose or carnation; (2) those which give earlier or increased flowering or both, as stock, aster, Shasta daisy, or pansy; and (3) those which are delayed in flowering by lights, as the perennial chrysanthemum.

PLANT FORCING WITH ELECTRIC LIGHTS

ROBERT B. WITHROW
Department of Horticulture

During recent years a great many experiments have been carried on dealing with the practical commercial application of artificial lights for forcing greenhouse crops. The reported experiments which have been most successful economically are those in which electric lights have been used at night to supplement daylight.

The two points of interest which are forwarded in a discussion of a commercial installation of lights for forcing have to do with, first, the equipment necessary and, second, the results which may be expected with various crops. This paper is designed to give a brief discussion of equipment installation, and a resume of the results of recent experiments using artificial lights over a number of plants. This circular is based upon four years of experimental work at the Purdue University Agricultural Experiment Station and upon the experiences of other investigators, as noted at the end of the paper.

The entire subject is still in the experimental stage and it is impossible to set down the final word as to cultural recommendations. Therefore, it is to be realized that, as new knowledge of the subject is acquired, many of the recommendations given here may need to be changed.

The most outstanding fact which has come out of the research work of the last few years is that many crops will respond to very low light intensities with earlier or increased flowering, or both. A 40-watt lamp placed in a suitable reflector three to five feet above the bench will produce sufficient light for most responsive crops and for many a 25-watt, or even a 15-watt, lamp is above the value needed. With the beneficial responses which have been observed with these low intensities, the cost of electric power becomes a small item.

When lights are being applied over any seasonal crop for the first time, the use of adequate check plots cannot be too strongly recommended. They serve a very definite purpose for the grower who is just beginning to use lights. They show him what the plants would have been without the lights, giving him the exact value of artificial lighting. Such plots prevent him from crediting the lights with either undesirable or exceptionally good growth, if such is not due to lighting.

By an adequate check plot is meant a small plot, not less than five or six feet of bench space, which receives no additional light. It should have, as nearly as possible, the same growing advantages as the lighted group and be similar to it in all respects except for lighting. The check plot should be carefully curtained to exclude any direct or stray radiation from the lamps in adjoining plots. Black oilcloth, tin, or wood may be used to screen out the direct light and black cloth may be used to keep out light reflected from the glass roof, the floor, and such.

It is not suggested that space be used for check plots in the case of out-of-season crops which normally fail to flower satisfactorily during the wintertime.

In general, desirable results may be obtained by applying the lights at any time during the night which is most convenient. They should be on from four to ten hours beyond the normal daylight period, and six hours represents a good average. It is not practical to use artificial lights during the day.

Equipment Suggestions

The selection of proper reflectors for plant irradiation is very important if the minimum power consumption is to be obtained. Many of the cheap, conical, tin reflectors on the market are wasteful of light and, to secure a given light intensity at the bench, a higher wattage lamp is necessary than with an efficient type reflector. The distribution of light over the bench is also poor with the conical type. Probably one of the best reflectors which is available at present for this type of work is the RLM, obtainable from most manufacturers. This gives a uniform distribution of light and reflects most of the light downward. The next best is the bowl type, which is somewhat cheaper than the RLM, but not quite so efficient in light distribution. A good working rule for the selection of a reflector when the characteristics are not available is to secure that reflector in which no portion of the lamp bulb extends beyond the outer rim. A suggestion for a very cheap, homemade reflector is a 10 or 15 cent alumnium cake pan 6 to 8 inches in diameter and 2½ to 3 inches deep. A hole is cut in the middle to take the lamp bulb neck. The pan should be sufficiently deep so that, when it is allowed to rest on the spherical portion of the bulb, the outer rim extends below the bottom of the lamp.

For the most efficient operation, the reflectors should be kept clean. Routine cleaning every month or two is advisable.

Ordinary incandescent Mazda lamps of either clear or inside frosted glass may be used. The blue glass daylight Mazda lamps are not recommended for this type of work as yet. They are expensive and the results to date do not justify the added cost. The so-called sun-lamp, which has a very useful field of application in medicine, is not suggested for use under the conditions discussed in this paper. Most of these lamps produce the shorter wavelengths of ultra-violet light, which, if left unscreened, are certain to severely injure any plants subjected to them for the periods of time recommended in this paper. Ultra-violet radiation some day may have a place in the forcing of crops, but the results up to the present time are too conflicting to warrant commercial use.

The lamp wattages recommended later are given for use with a good type bowl or RLM reflector, the reflectors spaced six feet apart and placed three to four feet above the bench, kept at least two feet above the tops of the plants. These values are satisfactory with the above-mentioned conditions only. The grower who wishes to use one row of lamps to irradiate two benches or who desires to use the more efficient 500- or 1000-watt lamps to light an entire house, should use an illuminometer, such as a portable sight-meter, to determine lamp spacings and heights. Five-hundred-watt and 1000-watt lamps are approximately two times as efficient per unit of electrical power consumed as the lower-wattage lamps. This, together with the cheaper cost of installation due to the fewer units involved, makes the higher powered lamps more economical for irradiating large areas.

The value of minimum intensity given later, under cultural suggestions, should be maintained under all conditions, regardless of the method of lighting. Higher values will produce somewhat better results in most cases, but these are not generally commensurate with the additional power consumed. If lighting conditions other than those outlined here are applied, an illuminometer should be used to check the minimum intensity and the proper lamps selected to maintain the recommended value. Most local utilities companies have available sight-meters to measure light intensity in terms of foot candles,* and they probably will be glad to assist the grower.

CORRELATION OF LAMP WATTAGE AND FOOT CANDLE INTENSITY

Lamp Wattage	Light Intensity Foot Candles
15	1
25	2
40	5
60	7
100	15
200	30
500	75

---

* A foot candle is a unit of measurement of visible light intensity.

The values presented in the above table are the minimum ones on a five-foot bench when the above wattage lamps are used in an efficient, bowl-type reflector placed 40 inches above the bench and six feet apart. These values are approximate, since they take into consideration deterioration of the lamps and such factors, which decrease the efficiency of the unit with use.

While it is readily possible to turn lights on and off manually, it is more desirable to install time switches which may be had in a number of types and prices. The cheaper clocks require setting each evening while the more expensive electric, motor-driven kinds are automatic. Since these switches are so low in price, it is considered hardly worth while to manually operate the lights.

Cultural Suggestions

In the following remarks, an endeavor has been made to present the optimum lighting conditions for each crop discussed and to give the general results that may be expected from the use of artificial radiation. A number of crops are listed which have not responded profitably to light. These crops often give increased production or earliness with the use of added illumination but the response has not been great enough to warrant the cost of lighting. Their listing in the unfavorable group does not indicate that further experimentation may not prove them good for winter forcing with light. To the contrary, in the future, many of these may be found to be very good, by the use of other cultural variations.

Artificial radiation, in many cases, tends to inhibit the development of laterals so that the plants may be placed from one-half to two-thirds the ordinary spacing. The usual disbudding practice should be applied to the lighted plants.

Lighting generally tends to inhibit root development and it is advisable to delay its application until the young plant has produced a strong root system and made a vigorous vegetative growth. For most annuals this is usually between one and two months from germination. For the best flowering results lighting should not be deferred too long, as most plants become less sensitive as they grow older.

With some plants, such as the China aster and dahlia, the flower color in the wintertime, when forced with lights, generally comes lighter than during the normal flowering season. This should be taken into consideration in the selection of varieties where color is an important factor.

Standard cultural practices are followed in all cases unless otherwise noted.

Blue Laceflower (Didiscus coeruleus)

Earlier and more profuse flowering occurs in the case of blue laceflower, under lights. The stems are apt to be short in the lighted condition, however, especially when the plants are forced very early. Five foot candles or 40 watts may be used.

Butterfly Flower (Schizanthus pinnatus)

Schizanthus produces a tall, weak plant and poor flowering under lights, although the flowering date is hastened. The flowers, however, are satisfactory for cutting purposes.

Calceolaria (Calceolaria hybrida)*

Calceolaria flowers much earlier if lights are used. Some lighted plants flowered February 12, as compared with the checks which blossomed on March 26. It has been indicated that lights may be applied with very favorable results as the plant approaches maturity. Five to seven foot candles or 40 to 60 watts should produce the desired result.

---

* The plants which are starred have been found to produce the best responses to supplemental artificial radiation.

Calendula (Calendula officinalis)

Calendula does not appear to respond to light except with an increase in stem length. Most varieties produce longer stems with only a few weeks of irradiation immediately preceding flowering. Lights may be of value as an emergency measure over Calendula to increase stem length on a crop in which the stems tend to be short. This same practice holds with a number of plants which do not otherwise respond. An intensity of five foot candles at the bench, or a 40-watt lamp may be used.

Calla Lily (Zantedeschia aethiopica)

Calla lily did not respond to artificial light as a supplement to daylight, under the experimental conditions used.

Carnation (Dianthus caryophyllus)

Carnation gives increased flowering with added light in the case of some varieties. Pink Abundance and White Matchless both give about 25 per cent more flowers when lighted. Longer stems are also produced under the lighted condition.

An undesirable feature noted when Pink Abundance was irradiated was the decrease in new shoots at the end of the season, as compared with the control. This same result has been observed with other varieties.

On the whole, experiments to date indicate that the carnation is not a profitable crop for this type of forcing.

China Aster (Callistephus chinensis)*

This is a crop which responds remarkably well to lights for both winter and summer forcing. Increased stem length and earlier flowering are evidenced by most varieties in either case. A few varieties do not respond as well as others and are not so well adapted for forcing.

Winter Forcing

Experiments using various light intensities over the Heart of France variety indicate that low intensities produce nearly as desirable results as far as flower production and earliness are concerned as do much higher intensities. The stem length is less, however, with lower intensities. The results secured indicate that stem length is somewhat proportional to intensity. This is also true of flower diameter.

Special care must be taken with aster when cultured with lights during the winter. The plants must be irradiated for a sufficient number of days if good stems are to be secured. A short period of lighting brings on the earliest flowering but the stems are usually not of sufficient length for the market. At least three months should be planned as a minimum period and a longer time may be desirable. A good rule is to keep the lights on until the stems have reached the desired length.

Wilt resistant varieties should be selected and proper seed and soil sterilization treatment followed. A moderately cool house is best for this crop, when possible, since, at temperatures below 50 to 60 degrees Fahrenheit, the organism responsible for aster wilt is unable to develop to a marked degree.

A light intensity of one foot candle, or a 15-watt lamp, is sufficient for aster. Higher intensities may be used with an increase in stem length and flower diameter produced.

Some varieties which may be used for winter forcing with good results include American Branching Phlox Pink, Comet Type Dark Blue, California Giant Light Blue, Early Royal Shell Pink, Early Royal Purple, Giant Comet Light Pink, King Type Lavender, and Heart of France. Professor Alex Laurie of Ohio State University (2) has indicated that Crego, Purity, Daybreak, and Lavender Gem also give good results. He secured December flowers from a September planting of Sunshine aster.

Queen of the Market varieties respond to light but the stems are apt to be weak and the flowers small. Sunshine Lilac also responds somewhat but the stems are usually too short.

Good normal blossoms may be expected when lights are used. Without light a large percentage of abnormal flowers are produced.

Summer Forcing

For summer flowering field crops, earlier blooms may be induced by a few weeks irradiation while the seedlings are still flatted (4). This is very economical and gives good financial returns with some varieties. Early Royals respond well but the Queen of the Markets again produce poor quality flowers when lighted. One or two foot candles or a 15-watt lamp is suggested.

Chrysanthemum (Chryanthemum sp.)*
Perennial:

With chrysanthemum, rather than hastening the crop with lights, irradiation delays flowering. Contrary to first impressions, this is profitable from a financial viewpoint since good flowers may be secured in December, January, and February.

Pink, white, and yellow mistletoe mums were irradiated for 45 nights from October 4 (6). Temperatures of 40 and 50 degrees were used, the later flowers produced by the lower temperature. The demand for the blossoms was great, both wholesale and retail markets taking the entire crop at a premium return. A minimum intensity of five foot candles or a 40-watt lamp is probably sufficient for this crop.

Annual

The annual chrysanthemum responds to irradiation with earlier and increased flowering and longer stems. The burridgeanum variety is good. An August seeding produced December flowering. Other annual varieties also respond well. Five foot candles or 40 watts is recommended.

Cornflower (Centaurea cyanus)

Cornflower blooms more quickly and has longer stems under lights, but a decrease in the number of blossoms over the check has been noted. This is probably not a very good forcing crop.

Corn Marigold (Chrysanthemum segetum)

Lights brought about an increase in flower production and earliness. In one case, the irradiated group produced twice as many blossoms as did the control and flowered almost two months earlier. Five to seven foot candles or 40- to 60-watt lamps may be used.

Cineraria (Cineraria sp.)

Cineraria Columbia mixture and C. multiflora flower several weeks earlier with lights but the time saved seems to make the cost of irradiation scarcely worth while. C. cruenta flowered over three weeks in advance of the check. Cineraria is inclined to be spindling when forced.

Clarkia (Clarkia elegans)

Clarkia responds with earlier flowering and longer stems. Care must be taken not to light the plants too early, since weak stems are apt to develop. A good vegetative growth should be established before the plants are irradiated. Use a minimum of five foot candles or 40 watts.

Coreopsis (Coreopsis sp.)*

A month or more earlier flowering and a very noticeable increase in flower production have been secured with lights in the case of C. grandiflora. C. tinctoria also blooms much earlier. Five foot candles or 40 watts should be sufficient to produce very desirable results.

Crown Daisy (Chrysanthemum coronarium)

Earlier and more flowers may be produced with crown daisy by the use of lights. Five to seven foot candles or 40- to 60-watt lamps may be used.

Cyclamen (Cyclamen persicum)

Cyclamen responds to light but the differences do not warrant the installation. Backward plants may be hastened by using lights, however.

Dahlia (Dahlia sp.)*

Most varieties of dahlia bloom earlier and more profusely with lights. This is especially true of the large-flowered type. Longer stems and larger flowers are the rule. Good flowering has not been secured with the smaller pompoms.

Of the large varieties, Jersey Beauty, Ida d. ver Warner, and Papillon respond well to lights. Four foot candles or 40 watts is sufficient intensity. Ground beds are the best culture method, since these plants often reach heights as great as eight or ten feet.

Little Belle and Tommy Keith of the smaller-flowered varieties respond to lights but they do not flower freely and hardly seem desirable for winter culture until more worth-while results have been secured.

The keeping qualities of the dahlia do not appear to be improved by winter forcing.

The recommended intensity is five to seven foot candles.

Delphinium (Delphinium sp.)

Results obtained with lights over delphinium scarcely warrant their use, although earlier and increased flowering were secured with the belladonna variety. D. hybridum responds only slightly to lights. D. ajacis gives greater production under lights due to longer laterals.

Feverfew (Matricaria capensis)*

Excellent results have been obtained with feverfew. More flowers are produced and they have been secured almost two months in advance of the check group. This crop may follow mid-season mums and clumps from the out-of-doors plants may be used. When lights were used, flowers were secured from cuttings transplanted in early January for Easter and Mothers' Day, while the controls flowered barely in time to be cut for Memorial Day. Five foot candles or 40 watts is recommended.

Freesia (Freesia hybrida)

Freesia responds adversely to light, a reduction in number of blooms occurring. The lighted crop and the controls bloomed at about the same time.

Gaillardia (Gaillardia sp.)*

Earlier and increased flowering and greatly increased stem length are produced with lights over G. grandiflora. With G. lorenziana, increased production and earliness was evident, although the stem length was somewhat less than in the control group. The suggested intensity is five foot candles or 40 watts.

Gladiolus (Gladiolus sp.)

So far, gladiolus has not responded profitably to lights. All varieties have not reacted favorably. Those which did respond increased so slightly in production, under the conditions used, that the results were not sufficient in return to equal the cost of power. However, further experimentation may produce very good results.

Iris (Iris tingitana)

Dutch iris, variety Wedgewood, produced a 50 per cent difference in flowering in favor of the lighted plants. Longer stems were secured in the irradiated group. Eight to 15 foot candles or 75- to 100-watt lamps are recommended as a minimum, in this case.

Leptosyne or Sea Coreopsis (Leptosyne maritima)

The only advantage to be gained with Leptosyne by irradiating is earliness in blooming. With an intensity of five foot candles or 40 watts, over a month may be saved in flowering time.

Lily (Lilium sp.)

The forcing of lily by means of lights has been the subject of much experimentation. With high intensities, favorable results have been obtained by using lights for a few weeks to hasten flowering. The use of lamps of as low as 100 watts, with favorable decrease in flowering time, has been reported. The results have been various with low intensities, however, at Purdue. The flowering time has not been decreased by more than one to two weeks, by the use of 10 foot candles. L. giganteum and L. erabu were irradiated. L. harrisi has been lighted also, with no better results.

No less than 30 foot candles or 200 watts is recommended, and higher intensities should give proportionately better results. Temperatures should be kept very favorable, even with irradiation.

Marigold (Tagetes signata pumila)

Dwarf marigold responds well to lights. Increased flowering is secured by irradiating for approximately 60 days just after benching or potting from the flat.

The dwarf variety, Legion of Honor, makes an excellent potted plant, being bushy and symmetrical. When it is in full flower, it compares favorably with many potted species. Five foot candles or 40 watts is advised.

Nasturtium (Tropaeolum majus)*

Golden Gleam nasturtium does exceptionally well under lights with twice as many flowers produced as the controls, in several sets of investigations. Almost a hundred flowers per plant were produced in 2½ months of blooming under lights, in one instance. The plants were still blooming freely when they were discarded. An intensity of five foot candles or 40 watts is satisfactory.

Pansy (Viola tricolor)*

Pansy is doubtless one of the most excellent crops for forcing with lights. Flower production has been increased as much as sixteen times with light, in the case of the Giant Swiss Blue variety. This is an average of 52 flowers per plant in less than a three-month blooming period. It is a maximum production, of course, but ten or more flowers per month per plant may be expected ordinarily. Longer stems and earlier flowering also occur, often as much as two months being saved in flowering time. This depends somewhat on the date of seeding.

Other varieties respond with very good results. Those grown under lights at Purdue, other than the Giant Swiss Blue, include Giant Azure Blue, Giant Eros, Giant Pure White, Giant Swiss Alpenglow, and Swiss Yellow.

It should be noted that high flower production is secured with pansy only while irradiated. Discontinuance of lighting usually causes a decrease in flowering.

The effect of light intensity on pansy has been investigated and good results have been obtained with one foot candle or a 15-watt lamp. However, higher intensities give proportionately better results. Five to seven foot candles or 40- to 60-watt lamps is advised.

Primrose (Primula obconica)

Indications are that primrose does not give a favorable enough response to warrant the use of lights.

Rose (Rosa sp.)

Rose has not been found to respond profitably to the application of artificial lights. One-hundred-watt lamps and 1000-watt lamps were used. The results were negligible with the lower intensity, and the response was not great enough to be profitable with the higher wattage.

Salpiglossis (Salpiglossis sinuata)

Longer stems and more and earlier flowers are produced when Salpiglossis is subjected to light.

Scabiosa (Scabiosa atropurpurea)*

Longer stems, much earlier flowering, and greater flower production occur with Scabiosa under lights. It is a good species for forcing, if care is taken to allow a sturdy vegetative growth to develop before lights are applied. Otherwise, a decided tendency toward weak stems is evidenced. Five foot candles or 40 watts may be used.

Shasta Daisy (Chrysanthemum maximum)*

Shasta Alaska daisy is extremely worth while under lights. January flowers should be secured by placing lights over the plants in November. Summer field stock may be used. Longer stems and more than 150 per cent increase in flowering have been secured by the use of lights. Exceptionally large flowers are also the rule in winter blooming. Five foot candles or 40 watts is the suggested intensity. Control plants usually do not bloom until later, a difference of one to two months or more in flowering time.

Shirley Poppy (Papaver rhoeas)

This poppy responds with a good number of blossoms and long stems when lights are used. Five to seven foot candles or 40- to 60-watt lamps should be sufficient to secure good results. The control plants did not blossom during the winter months.

Snapdragon (Antirrhinum majus)

Much more profuse and earlier flowering is evidenced in Snapdragon under lights but the stems are short and not so heavy as is desirable for a first-class flower. Cheviot Maid, Suntan, and Rose Queen all respond in a more or less similar fashion.

Lights could hardly be considered profitable for this crop, unless short-stemmed spikes are acceptable for some particular use.

Stock (Matthiola incana)*

Good results may be expected with stock under artificial radiation conditions. Earlier flowering and slightly longer stems are secured with most varieties. Beauty of Nice, Perpetual Branching, Bismarck Lilac Lavender, and Golden Ball all respond favorably to lights.

Stock does better with higher intensities than with the lower ones, the decrease in flowering time being somewhat proportional to the intensity. Eight to 15 foot candles or 75- to 100-watt lamps may be recommended. About a month's decrease in flowering time may be expected with this intensity. Seedlings planted in August and benched in September should give late December or early January flowers. Lights should be discontinued as soon as buds are formed. Professor Laurie states that columnar stocks respond to as low as 2 foot candles or 25 watts.

Sweet Pea (Lathyrus odoratus)

Slightly increased flowering occurs with some varieties of sweet pea when forced with lights. However, in other varieties, no differences have been noted.

An interesting variation is the summer flowering type. Results indicate that the summer blooming Pinkie responds very favorably to artificial light, with the production of a much earlier crop in late January or early February. So far, there are no indications that this variety can successfully compete with the winter types in flower production during the winter season.

To date, the data obtained at Purdue have not shown any consistent influence of low intensity lights on bud drop. Other workers have found a decrease with higher intensities, but the decrease has not been commensurate with the power cost.

Sweet Sultan (Centaurea imperialis and Centaurea suaveolens)*

Centaurea imperialis blooms earlier and a large increase in the number of flowers has been noted. However, a tall, weak plant is secured, unless it is allowed to establish a vigorous vegetative growth before lights are applied. C. suaveolens gives slightly increased flower production and much longer stems under lights. Five foot candles or 40 watts is advised.

Violet. (Viola sp.)

Earlier and increased flowering have been obtained by the use of artificial lighting over blue violet. Five foot candles was the intensity used.

Yarrow (Achillea millefolium rosea)

The use of lights brings Achillea into bloom about a month sooner than the control and the stem length is materially increased. Five foot candles or 40 watts has been used with success.

Zinnia (Zinnia elegans)

Zinnia has reacted unfavorably to lights so far. Both check and irradiated plants evidenced poor growth and flowering, with weak stems and small flowers. Although it seemed that this plant should be an excellent one for winter forcing, the low intensities used did not produce desirable growth.

Miscellaneous Crops Unfavorable for Forcing

Crops not listed previously, which have been subject to investigation and which have not been profitably forced with light, under the conditions used, include:

Achyranthes brilliantissima
Aquilegia hybrida
Anemone sp.
Arctotis grandis
Asparagus plumosus
Asparagus sprengeri
Cosmos bipinnatus
Cynoglossum amabile
Digitalis purpurea
Dimorphotheca aurantiaca
Erlangea tomentosa
Erysimum perofskianum
Felicia amelloides
Hunnemannia fumariaefolia
Hyacinthus orientalis
Iberis umbellata
Ipomopsis elegans
Iresene herbsti
Ixia maculata
Kniphofia pfitzeriana
Muscari botryoides
Narcissus poeticus ornatus
Narcissus psuedonarcissus
Narcissus tazetta
Ornithogalum lacteum
Pelargonium zonale
Pyrethrum hybridum roseum
Ranunculus sp.
Statice latifolia
Statice suworowi
Tulip gesneriana hybrids

The author wishes to express his appreciation to Doctor Laurenz Greene, Professor E. R. Honeywell, Professor Alex Laurie, and Mr. L. C. Porter, who have very kindly offered valuable criticisms in the preparation of this circular.

INDIANA BALTIMORE TOMATO—ITS HISTORY AND DEVELOPMENT

This field of Indiana Baltimore tomatoes yielded over 17 tons of red ripe tomatoes per acre. With good seed large yields of high quality are possible on many Indiana farms.

UNIVERSITY OF ARIZONA LIBRARY

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

With the location of the tomato seed project at Purdue University, there has developed a mutual interest and cooperation between the Experiment Station and the Indiana Canners in problems related to the tomato canning industry. The benefits from these efforts have assumed State and National importance. Outstanding results of this research are:

1. Production of a strain of tomatoes with the capacity to produce more tomatoes per acre than any other variety under Indiana conditions.
2. A seed treatment was developed to prevent the spreading of bacterial spot on the seed.
3. A practical knowledge of bacterial canker and the importance of disease free seed to prevent its spread.
4. A scientific method of color measurement as applied to tomatoes and tomato products.
5. The importance of quality initiated a method of buying the raw product on a graded basis.
6. Field investigations have emphasized the necessity for careful picking.
7. In the past seventeen years, nine hundred eighty other strains and varieties have been compared with the Indiana Baltimore.

INDIANA BALTIMORE TOMATO—ITS HISTORY AND DEVELOPMENT

Edw. C. Stair
Purdue University Agricultural Experiment Station

Indiana has for many years been one of the leading States in the tomato canning industry. Tomato production has made a steady and rapid increase as evidenced by the fact that over 80,000 acres of tomatoes were grown for the canning factories of the state in 1934.

Early in the development of the industry, canners and farmers were often disappointed in the quality of the canned product obtained from the seed planted. The seed was not dependable and frequent low yields resulted. Experiment Station workers in cooperation with leaders in the industry studied the situation and concluded that a better strain of tomato seed of fixed quality and yielding capacity was urgently needed.

The yielding ability of the tomato as well as any other crop is determined by two main factors, environment and heredity. Environment fluctuates with the season, fertility of the soil, rainfall, amount of manure and fertilizer used, temperature, cultural practices, and many other factors. Heredity, on the other hand, when once fixed within a pure line, is usually very stable.

Scientific research has pointed out that considerable variation may be expected to exist within any population of plants propagated from seed, and that continuous selection together with careful seed saving methods is necessary in order to keep any variety at its best. In tomato improvement work, the experimenter must be very familiar with varieties and types because if one off type plant or one plant of another variety is allowed to develop in a seed field, it dilutes the purity of the strain very rapidly. A single tomato fruit may contain as many as one hundred fifty seeds and a single plant may produce from thirty to sixty fruits that actually ripen and get into the seed.

Continuous cooperation between the Agricultural Experiment Station and the Indiana Canners led the Canners to appoint a seed committee in 1917 authorized to study their seed situation and to make plans for its improvement. As the result of the efforts of the Experiment Station workers and of this committee, the foundation was laid for the development of a strain of tomatoes better suited to their needs.

History

The first problem to decide was what variety would be best suited for canning purposes under Indiana conditions. A large number of varieties had been tried from year to year by various canners, and at the time this work

started the two varieties that predominated in the state were Stone and Greater Baltimore. In 1918 seed was secured from the originators of these two varieties in sufficient quantity to plant twenty acres of each. The two varieties were almost equal in every respect, except that the Baltimore was somewhat earlier which was a factor decidedly in its favor. An individual plant selection was made from this field in 1918 and it was from this start that the variety now known as the Indiana Baltimore was developed. In Figure 1, page 4, this selection is shown as Accession No. 18. This original plot was located near Indianapolis.

Many selections have been made in the past seventeen years, but for various reasons all except fifteen have been discarded. Thirteen of these came from the original selection made from Accession No. 18. Strain number 2161 was made in 1921 at Bowling Green, Ohio, from a strain of Greater Baltimore that was very satisfactory under conditions there. Strain 2170 originated in 1924 as the result of crossing two strains of Indiana Baltimore.

The seed plots were located at Indianapolis again in 1919, but at a meeting of the seed committee with representatives of the Agricultural Experiment Station early in 1920 it was decided to move the bulk seed plots to a small canning plant in southern Indiana and to move the record and breeding plots to Lafayette. In 1921 the bulk seed plots were moved to another southern Indiana factory where they have remained since. In 1931 a northern Indiana location for bulk seed plots was added. The breeding work, experimental and record plots have remained at Lafayette for the past fifteen years. Here it was found possible to give closer supervision to the work than if located elsewhere. In this time many research problems involving the use of greenhouses and research laboratories, in addition to the field plots, have been completed and the Indiana Baltimore tomato is now a practically pure strain capable of producing high yields of very good quality.

During this time the members of the Indiana Canners' Association have been given an opportunity each year to *emphasize* their ideals regarding the selection of types of tomatoes best suited to the industry. This has been made possible through various inspection trips at which times the members of the seed committee and the Experiment Station workers went over the record plots at Lafayette as well as many acres of the bulk seed plots at the canning factories.

Development of the Indiana Baltimore

Individual selections made each year are known as strains. The progeny from these individually selected lines are thrown together each year and the combination of these strains makes what is known as the Indiana Baltimore variety. This variety at the present time consists of fifteen strains as shown in Figure 1, page 4. Originally each strain started from an individual plant each year, but at the present each strain starts from an individual fruit each year. Hundreds of individual selections have been made during the development of the Indiana Baltimore. These selections are planted in triplicate in the record plots where plants as well as fruits may be carefully studied. Only the best of these are carried on to the multiplication plots, the remainder are discarded. In making the individual fruit selections each year, plant characters, as well as the most ideal fruits regarding type, shape, color, and internal characters, are considered. The various steps necessary from the time the individual fruit is selected until the seed has been multiplied in sufficient quantity to reach the growers' fields in the State are outlined on the inside of the back cover page.

Field Plot Arrangement

The field plots at Lafayette are arranged each year so as to overcome differences due to soil variation. The arrangement as shown in Figure 2, page 7, was employed in 1934 As shown here, the yield record plots were located at one end of the field. The fifteen strains were planted in these plots in triplicate. In Figure 2 these replications are designated by the letters A, B, and C. The seed in each case came from an individual fruit which was the most perfect that could be found the previous year. Plant and foliage characters were also considered when these selections were made. Each fourth row is a check row. The seed from which these check plants were grown came from bulk seed from the multiplication plots last year. These check rows are used as a basis for comparing the individual strains each year.

The field in which these trials were conducted in 1934 was five acres in size. The record plots required only a small part of the area. The remainder was divided into fifteen equal parts as shown in Figure 2, and it was here that the seed was multiplied in sufficient quantity to plant the larger multiplication fields at the canning factories where the seed is produced for the Indiana Canners' Association. The seed for planting these larger multiplication plots at Lafayette is obtained from the record rows which originated from an individual fruit the year before. The plants in all plots are set five feet apart in the row and the rows are planted six feet apart. These distances are almost double those recommended for field practice, but the greater distance is found necessary where individual plants are to be studied and also to make sure that pickers will keep the fruits from each plot separate. Even at these greater planting distances, yields at the rate of fifteen to twenty tons per acre have been obtained.

The strains are kept separate in the multiplication plots at Lafayette each year, as indicated in Figure 2, so that if any unexpected difficulty should occur in any strain it could be eliminated without interfering with any of the other strains.

Methods of Measuring Improvement in Yield and Quality

Anyone walking through a tomato field of one variety will find it difficult to see differences between individual plants. All plants look practically alike. The fruits on one plant are similar to those on all other plants. The only way to detect small differences is to measure accurately all essential

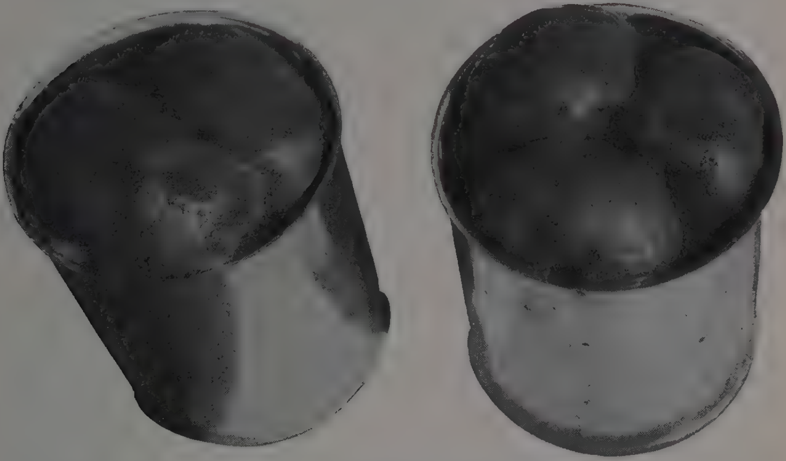
factors. A large number of individuals must be measured in order to get a fair idea of the entire population. These measurements when studied under approved statistical methods by a well-trained experimenter help him to draw reliable conclusions relative to the groups of plants with which he is working.

A sample sufficiently large to give reliable results is measured each year from all Indiana Baltimore strains, as well as samples from other varieties that are brought in to compare with it. Measurements of this kind have been taken each year since the work was started on this variety. Such measurements accumulating over a period of years give figures that can be relied upon with reference to plant and fruit characters. It is on the basis of these figures after careful study that some strains are dropped and others are added.

Indiana Baltimore with a high percentage of U. S. No. 1 tomatoes. Uniformity of size, shape and color improve the quality of the canned product. The first step was good seed.

Testing Varieties Adapted to Indiana

Each year a large number of other varieties from seedsmen and plant breeders throughout the country are tested in isolated plots to determine their yielding ability and performance under Indiana conditions. Every fifth row in these plots is a row of Indiana Baltimore which is used as a check. No seed is saved from these plots. In the seventeen years since the Indiana Baltimore was originated, nine hundred eighty other strains and varieties have been compared in this way with it. These plots and the results from them are open to inspection by the seed committee of the Indiana canners each year. When anything is found that appears to surpass the Indiana Baltimore under Indiana conditions, it is given a thorough trial.



Quality in the can, Indiana's goal. Indiana Baltimore seed has been developed to help put better quality in the can.

Development of New Varieties and Strains

A part of any good seed development program is the development of new varieties and strains. In the making of new hybrids it is often possible to combine the good characters of two or three varieties into one new variety which will be better than any of its parents. In connection with the Indiana Baltimore work, a number of new hybrids have been developed each year. An effort is always being made to secure disease resistant strains, some that are earlier and some that are later than others, together with improvement in yield, quality, and type.

The Characteristics of Good Tomato Seed

Good tomato seed is not based on cost, but on what it will do under the conditions where it is grown. The qualifications of good tomato seed are:

1. It must produce a good quality of finished product and a good yield;
2. It must be free from disease;
3. A large percentage of the seed must produce good strong plants;
4. It must produce fruits true to the type which it represents;
5. It must not be mixed with seed of any other variety; and
6. It must be clean and free from foreign matter.

The canner who buys low grade seed not only cheats himself in that he often receives a low grade finished product, but there is also a financial loss for those who produce the raw product. High yields can not be expected from low grade seed.

Seed Certification

In 1934 Indiana launched a new project of certifying tomato seed. This work is done under the authority of the State Entomologist cooperating with the Purdue University Agricultural Experiment Station. The qualifications which have to be met before seed can be sold as "certified" are very rigid. The source of the seed must be known and approved. The plant beds must then be certified before the seed can be sown. A qualified inspector must be on hand while the seed is being sown and again when the plants are pulled. The plants are all inspected for disease before going to the field.

The fields from which the seed may be saved must be given two thorough inspections; the last of which must be when sufficient fruits are ripe so that there may be no mistake regarding type. No field is eligible for certification that has more than one variety growing in it, and it must be sufficiently isolated from fields of other varieties to guarantee little chance for cross pollination. Not more than one seed stock can be saved at one extraction plant. A field can not have more than one tenth of one per cent of off type plants in it, and these must be pulled and destroyed before any seed is saved from the field. No seed is saved from any field in which bacterial canker is found, nor from fields having more than one per cent of wilt. The seed is inspected by a trained inspector while it is being extracted and dried, and again when it is cleaned and packaged for sale.

How Much Does Good Seed Cost Per Ton of Raw Stock?

The value of tomato seed depends on its ability to give a high yield of quality canned product per ton of raw stock, a high tonnage of raw product per acre, and a high percentage of germination.

A study of Table 1 will permit a canner to obtain a clearer conception of what he can afford to pay for a pound of tomato seed.

The cost of seed is directly in proportion to the percentage of germination and to the yield secured by the grower. Every canner has some growers who are better producers than others. If the canner furnishes his growers with seed that will germinate 90 per cent, his seed cost will be about five cents per ton of raw stock if he pays $1.50 per pound of seed and the grower produces one ton of raw stock per acre. The same canner can pay $8.00 per pound for seed and his seed cost per ton of raw stock will be the same for the grower who produces five tons per acre. Table 1 demonstrates also that the canner will have practically the same seed cost per ton of raw stock if he pays $2.00 per pound for seed giving 50 per cent germination as he will if he pays $4.00 per pound for seed testing 90 per cent.

Per cent Seed Producing Plants	Tonnage Yield	Cost of seed per pound in cents							
		50	100	150	200	300	400	600	800
		Cost in cents per ton of raw stock							
90	1	1.736	3.472	5.208	6.944	10.416	13.888	20.832	27.776
	3	.578	1.157	1.736	2.314	3.472	4.629	6.944	9.258
	5	.347	.694	1.041	1.041	2.083	2.777	4.165	5.555

	10	.520	1.041	1.561	2.083	3.124	4.166	6.249	8.333

Table No. 1.

The cost (in cents) of tomato seed per ton of raw stock as affected by price of seed, percentage of germination and yield per acre. (Based on 6,000 tomato seeds per ounce and 3,000 plants per acre.)

Another angle to this question which might be pointed out here is that seed which shows a low percentage of germination has undoubtedly been weakened by some cause. This cause may have been due to poor drying or storage conditions or disease of some kind. Whatever the cause, it is possible that the seeds which do germinate will not have quite the vitality of seeds from other lots which show a high germination percentage and for this reason probably will not produce as large a yield as plants grown from the more vigorous seed.

Methods of Procedure

Each strain of Indiana Baltimore is started from a single fruit every year. Improvements made by breeding and selection reach the growers' fields and Indiana packing plants the fourth season after they are made, as shown below.

1931 *Parent Selection*

An individual fruit was selected. Seed saved from this fruit was tested in 1932 at Lafayette and seed secured for the multiplication plots at Lafayette in 1933.

1932 *Test Plots*

Seed from the individual fruit selected in 1931 was tested in triplicated plots at Lafayette. Yield, plant characters, fruit type, freedom from disease, were tested and studied. Seed was saved for the 1933 multiplication plots at Lafayette. Indiana Canners' Seed Committee inspected the plots.

1933 *Multiplication Plots*

The seed from the individual fruit selected in 1931, and tested in 1932, is now multiplied at Lafayette for the Indiana Canners' Association seed fields. Records and field plots are open to inspection for yield, quality, type, and freedom from disease, by seed certification authorities, as well as the Indiana Canners' Seed Committee. Seed supplied Indiana Canners for their 1934 bulk seed plots.

1934 *Bulk Seed Plots*

Seed was multiplied for general distribution at two selected canning factories. Plant beds were approved before the seed was planted. Seed was planted under supervision. Plants pulled and inspected for disease. Record obtained of fields planted. Record kept of replants. Fields were inspected previous to ripening and again before the seed was saved. Seed saving operations and packaging of the seed was supervised.

1935 *Growers' Fields*

Seed sold to various canners and used in production of canning crop tomatoes by growers.

* Indiana Crops and Livestock, 1934. Department of Agricultural Statistics.

TWENTIETH ANNUAL REPORT OF THE CREAMERY LICENSE DIVISION

T. H. Binney

March 31, 1934, marks the close of the twentieth year in which the Creamery License Division has had supervision over the testing in Indiana. A study of one of the tables in this report (Output of Licensed Plants in Indiana) will show the growth of the dairy industry during the past twenty years. In 1914 there were 355 licensed plants and stations while in 1933 there were 1,756. The number of licensed testers increased from 408 to 2,040 over the same period of time. Out of 41,834 testers' licenses which were issued only 168 of them were revoked. Forty-nine prosecutions have been made of persons or firms violating provisions of the Creamery and Testers' License Law. Fifteen thousand nine hundred and fifteen persons have taken the testers' examination. Out of this number, 12,968 persons passed and 2,947 persons failed to pass the examination. To examine this number of candidates 1,477 examinations have been held.

A total of 979,643 pieces of glassware have been calibrated; 976,982 pieces were found to be correct and 2,661 pieces were incorrect.

Indiana Dairy Statistics

At the time of applying for the renewal of creamery licenses, all creameries, milk plants, cheese factories, condenseries, etc., report the amount of butter, milk, cheese, or other dairy products made or sold during the year. With this information, together with figures supplied through a co-operative agreement with the United States Department of Agriculture, Bureau of Agricultural Economics, it is possible to compile reliable statistics concerning the total production of licensed dairy manufacturing plants.

The following table is a summary of the reports received from licensed plants for the years indicated:

Output of Licensed Plants in Indiana for 1914, 1923, 1932 and 1933

	1914	1923	1932	1933
Pounds of Butter	26,636,520	51,662,093	75,506,568	76,508,061
Pounds of Milk	51,067,066	213,578,850	505,210,133	463,359,717
Pounds of Cream	5,421,838	14,501,004	28,833,326	24,930,340
Gallons of Ice Cream	2,035,874	4,447,157	3,653,512	3,077,146
Pounds of Cheese	211,922	373,943	15,265,027	17,616,875
Pounds of Sweetened Condensed Milk	1,019,400	7,127,541	1,258,553	3,217,549
Pounds of Evaporated Milk	10,106,800	16,098,231	37,301,632	38,153,894
Pounds of Bulk Evaporated Milk	2,450,988	10,130,565	27,518,303	21,041,576

By comparing the figures for 1933 with those for 1932 in the above table, it will be noted that butter, cheese, condensed and evaporated milk show an increase while the remaining products show a decrease. The increase in the amount of butter made is 1,001,493 pounds, or 1.3 per cent. A total of 463,359,717 pounds of milk and 24,930,340 pounds of sweet cream were sold in licensed plants during the past year. This represents a decrease of 0.8

per cent of milk and 13.5 per cent of cream in 1933 as compared with 1932. The amount of ice cream manufactured during the past year shows a decrease of 576,366 gallons, or 15.7 per cent. Cheese production increased 2,351,848 pounds, or 15.4 per cent. Sweetened condensed milk increased 1,958,996 pounds, or 155.6 per cent; evaporated milk (case goods) increased 852,262 pounds, or 0.2 per cent, and bulk evaporated milk decreased 6,476,727 pounds, or 23.5 per cent.

In addition to the above products, dairy plants of the state manufactured 13,741,362 pounds of condensed skim milk; 419,116 pounds of evaporated skim milk; 998,403 pounds of concentrated skim milk (for animal feed); 5,542,705 pounds of condensed or evaporated buttermilk; 4,280,097 pounds of dried or powdered skim milk, and 1,689,311 pounds of dried or powdered buttermilk.

An estimate of the total amount of dairy products manufactured in the state may be secured by using the above statistics and estimating the amount of dairy products manufactured and sold in the plants which are not licensed. A large number of ice cream plants and market milk plants buy milk on a gallon or weight basis rather than on a butterfat basis and do not come under the jurisdiction of the Creamery License Division.

Amount of Butter, Milk, Ice Cream, Condensed Milk and Cheese Estimated as Produced in Indiana During 1933

Pounds of Creamery Butter	76,508,061
Pounds of Dairy Butter	10,408,105
Pounds of Milk Consumed	1,518,670,924
Gallons of Ice Cream	8,842,500
Pounds of Condensed and Evaporated Milk	62,413,019
Pounds of Cheese	17,616,875
Pounds of Cottage Cheese	2,816,234

By taking the amount of milk used in the manufacture of each of the various dairy products, the total milk production of the state may be calculated. In making this calculation, it has been necessary to estimate the amount of milk and cream consumed direct, the amount of dairy butter made, the amount of milk fed to calves, and the amount of milk lost on farms and in factories.

Total (Estimated) Milk Production

Creamery Butter Used	1,606,669,281 pounds
Dairy Butter Used	218,570,205 pounds
Milk Consumed Direct	1,518,670,924 pounds
Ice Cream Used	121,584,375 pounds
Cheese Used	174,187,090 pounds
Condensed Milk Used	156,032,547 pounds
Milk Fed to Calves	114,444,000 pounds
Milk Shipped Out of State	269,246,031 pounds
Losses on Farms and in Factories	125,382,133 pounds
Total	4,304,786,586 pounds
Milk Shipped in	167,585,079 pounds
Total Milk Production in Indiana	4,137,201,507 pounds

Creamery Licenses

Every creamery, shipping station, milk factory, cheese factory, or person, agent, firm, company, association or corporation, receiving, buying and paying, for milk or cream on the basis of the amount of butterfat contained therein, shall be required to hold a creamery license. (Section 6, Chapter 340, Acts of 1913, Indiana.) The license is issued by the Purdue University Agricultural Experiment Station upon complying with the provisions of the Indiana Creamery and Testers' License Law. Such license is valid for a term of one year unless revoked by the Purdue University Agricultural Experiment Station.

During the past year 1,756 creamery licenses were issued. This is an increase of four over the previous year's total of 1,752. Plant licenses show a gain of 12 in number, while the number of station licenses show a decrease of eight.

The following table is a summary of the number of kinds of plants issued creamery licenses during the year ending March 31, 1934, and for previous years, as indicated.

CREAMERY LICENSES ISSUED FROM 1928-1933, INCLUSIVE

PLANTS AND STATIONS	NUMBER AND YEAR					
	1928	1929	1930	1931	1932	1933
Butter	56	58	56	58	57	56
Milk	129	141	162	147	162	175
Ice Cream	11	16	18	16	12	14
Cheese	18	17	18	19	18	22
Condensed Milk	8	9	8	10	10	11
Butter and Milk	39	33	36	46	54	51
Butter and Ice Cream	17	13	10	13	9	11
Butter and Cheese	3	2	1	2	3	2
Butter, Milk, and Ice Cream	13	15	20	17	23	26
Butter, Milk and Condensed Milk	5	5	7	6	2	4
Butter, Milk, Ice Cream and Condensed Milk	7	7	6	6	7	5
Butter, Ice Cream and Cheese	0	0	0	1	1	1
Butter, Milk, Cheese and Condensed Milk	0	1	0	0	1	1
Milk and Ice Cream	24	18	19	26	25	19
Milk and Condensed Milk	2	5	4	5	4	3
Total number of Plants	334	344	369	372	389	401
Stations	1,614	1,588	1,524	1,457	1,363	1,355
Total Licenses Issued	1,948	1,932	1,893	1,829	1,752	1,756

The following table shows the number of plants which reported each of the five major products handled in licensed plants for the years indicated:

PRODUCTS	NUMBER OF PLANTS REPORTING						
	1927	1928	1929	1930	1931	1932	1933
Butter	142	140	134	136	149	158	157
Milk	202	221	229	257	254	279	284
Ice Cream	73	74	73	76	79	77	76
Cheese	9	21	21	20	22	22	26
Condensed Milk	24	24	30	28	31	25	24

Testers' Licenses and Examinations

To insure accurate tests to the producer and manufacturer licensed testers are employed by all plants and stations where milk and cream are bought on a butterfat basis.

Before securing a license an operator must pass an examination which consists of both laboratory and written work. The laboratory work consists of testing samples of milk and cream in duplicate; the written work consists of answering twenty questions which pertain to the testing of milk and cream.

Four hundred and twenty-one candidates appeared for the tester's examination during the past year. This is an increase of seventy-nine candidates over the previous year. Out of this number twenty-four failed to receive a passing grade; fifteen of the failures were due to unsatisfactory written work, six were due to laboratory work and three were due to both written and laboratory work.

Twenty hundred and forty testers' licenses were issued during the past year, a decrease of sixty-nine from the previous year's total of twenty-one hundred and nine.

The following table shows the number of candidates examined and testers' licenses issued for the year indicated:

NUMBER OF CANDIDATES EXAMINED AND TESTERS' LICENSES ISSUED FOR THE YEARS ENDING MARCH 31, 1920, 1924, 1928, 1933 AND 1934

	1920	1924	1928	1933	1934
Number of Individual Examinations	1,339	850	904	342	421
Number of Failures	226	125	290	20	24
Number of Persons Passing Examination	1,113	725	614	322	397
Number of Testers' Licenses Issued	2,371	2,518	2,661	2,109	2,040

The results of the seventy examinations which were held at the ten examination points in the state are given in the following table:

RESULTS OF TESTERS' EXAMINATIONS, 1933-1934

PLACE OF EXAMINATION	Number of Examinations	Number of Candidates	AVERAGE GRADES (PER CENT)		
			All Candidates	Candidates Passed	Candidates Failed
Lafayette	12	118	84.1	84.7	66.0
Muncie	6	53	84.1	85.9	66.6
Fort Wayne	7	72	85.0	85.9	64.0
New Albany	2	12	76.0	79.2	60.0
Evansville	6	33	78.7	79.6	65.0
Terre Haute	6	31	83.3	84.8	62.0
Indianapolis	6	44	84.6	86.1	63.7
North Vernon	4	32	83.9	84.3	72.0
Seymour	2	16	83.6	85.1	62.0
Plymouth	1	10	81.0	82.2	70.0
Totals	52	421	83.5	84.6	64.9

Glassware Inspection

The Indiana Creamery and Testers' License Law requires that all milk and cream test bottles, milk pipettes, and nine-gram weights, be examined for accuracy by the Purdue University Agricultural Experiment Station before being used in Indiana cream stations and dairy plants. All glassware conforming to the specifications given in Section 13 of the Law (Acts of 1913, Chapter 340) and found to be within the allowable tolerance are stamped with the letters "S. G. P." meaning "Standard Glassware, Purdue." The use of standard inspected glassware eliminates the possibility of incorrect tests from this source.

During the past fiscal year 43,006 pieces of Babcock testing glassware were examined by the Glassware Inspector of the Agricultural Experiment

Station. In addition, 271 nine-gram weights were inspected and all found to be correct. This is 8,927 pieces of glassware and 77 nine-gram weights more than were inspected last year.

The following table gives the amount of each kind of glassware inspected, and the number of pieces found to be incorrect:

GLASSWARE INSPECTION

KINDS OF GLASSWARE	Total Number of Pieces	Number Incorrect	Per Cent Incorrect
Cream Test Bottles	29,940	103	.344
Milk Test Bottles	11,184	2	.017
Milk Pipettes	1,882	0	.000
Summary	43,006	105	.244

Licenses Revoked

Inspectors of the Creamery License Division check the weights and tests made by operators of the Babcock test to determine their accuracy. If an operator is found to be testing incorrectly the inspector cautions him to be more careful in the sampling, weighing, and testing of milk and cream. Should later inspections show that incorrect testing is being done, whether intentionally or unintentionally, evidence is secured and presented to the State Creamery Examining Board at one of their regular meetings. At this meeting the operator is given an opportunity to explain the cause for differences between his tests and the tests made by the inspector. After careful consideration of the facts presented, the Board recommends to the Purdue University Agricultural Experiment Station the action to be taken.

During the past year the following testers were requested to appear before the Examining Board and, after considering the evidence, the Board recommended that their testers' licenses be revokd:

Miss Mabel Johnson, Scottsburg, Scott County, Indiana, tester for Red 73 Creamery Company, Union City, Indiana.

Mr. V. L. Ridenour, Curby, Crawford County, Indiana, tester for Armour Creameries, Louisville, Ky.

Mr. N. S. Hoskinson, Tennyson, Warrick County, Indiana, tester for Sugar Creek Creamery Company, Evansville, Indiana.

Mr. L. E. Johnson, Terre Haute, Vigo County, Indiana, tester for Johnson Butter Company, Terre Haute, Indiana.

Mrs. Marie Cole, Huntington, Huntington County, Indiana, tester for Schlosser Bros. Creamery, Fort Wayne, Indiana.

Mrs. Helene Sowers, Windfall, Tipton County, Indiana, tester for Schlosser Bros. Creamery, Frankfort, Indiana.

Mr. Edgar Hanson, Paoli, Orange County, Indiana, tester for Kraft-Phenix Cheese Company, Paoli, Indiana.

Mr. Lewis W. Hine, Monticello, White County, Indiana, tester for Golden Rule Creamery Company, Monticello, Indiana.

The Evolution of the Sirloin

UNIVERSITY OF ARIZONA LIBRARY

An Address By
PROF. C. S. PLUMB

"Some hae meat and canna eat
And some there be that want it
But we hae meat and we can eat
And for this God be thank'et."
—ROBERT BURNS

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

CHARLES S. PLUMB

Professor Emeritus in Animal Husbandry, Ohio State University.
Director of the Purdue University Agricultural Experiment Station from 1891 to 1902.

The Department of Animal Husbandry presents annually, in dramatized form, the knighting of Sir Loin, by King Charles II, at a special banquet to commemorate that historic event.

Professor Charles S. Plumb was chosen as the guest speaker for the occasion this year, and his manuscript records much of cultural and historic significance to those interested in animal husbandry.

THE EVOLUTION OF THE SIRLOIN

CHARLES S. PLUMB
Professor Emeritus in Animal Husbandry, Ohio State University

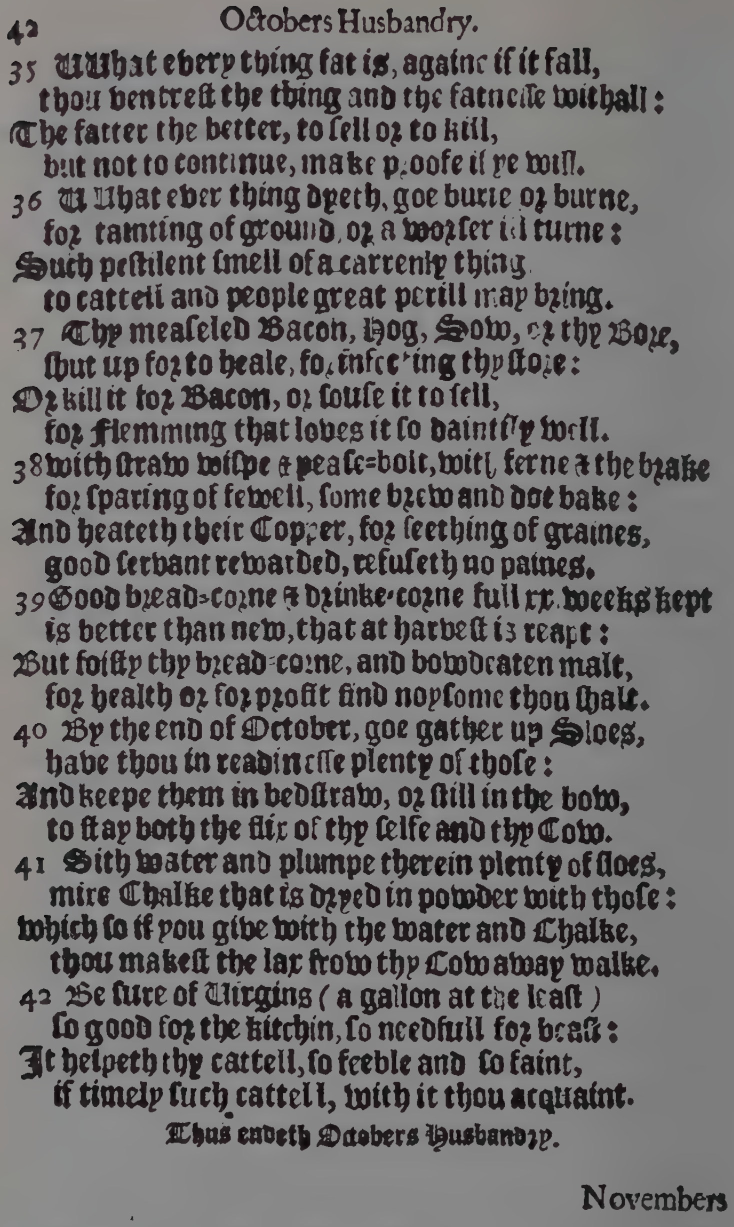
THIS is a story which will cover several centuries of English history. Perhaps you are already well informed of how the people of England originated and came into their own. However, I must remind you that it was invaded by the Romans under Julius Caesar before the time of Christ; was conquered by the Teutonic hordes of barbarians of Northern Europe, with tribes of Jutes, Angles and Saxons; and later subdued by the Normans, who established in the 11th century civilization and leadership for England. Thus it is apparent that very different lines of blood found root in that country. In spite of this, most Americans think all Britishers are built from a common stuff. Yet it is interesting to know that wide differences in speech and habits characterize the people in different sections of England. So broad is the dialect up in Yorkshire among those to the manor born, that a native Herefordshire man hearing it, thinks he is listening to a foreign tongue. While from an American viewpoint England is a small country, one finds in the different counties wide variations in speech, family habits or characteristics, and features of agricultural development.

If we wish to learn of the history of a country in any particular, it will be necessary to study the literature of the subject by consulting books in some form as a source of information. So in this connection let us make a study of the evolution of books, livestock husbandry, and the impress of great breeders; whereby a sirloin of supreme merit might be placed before The King.

While a number of documents were produced touching on agriculture in England as early as the fourteenth century, John Fitzherbert was the author in 1523 of the first book produced in that country which was on the subject of agriculture, or husbandry as it was then called.* Chapters on how to set out sheepfolds, to mow grass and make hay, to cause a ewe to love her lamb, as with also on cattle, horses and other stock, are given. He emphasizes the value of pastures, and in Chapter XIX, says of it: "And how many cattell it will grasse or finde by the yere, and what a beastes grasse is worthe by the yere, in suche a pasture." Fitzherbert also

---

* The Booke of Husbandry. By John Fitzherbert, 1523.



42 Octobers Husbandry.

35 What every thing fat is, againe if it fall,
thou ventreſt the thing and the fatneſſe withall:
The fatter the better, to ſell or to kill,
but not to continue, make proofe if ye will.

36 What ever thing dyeth, goe burie or burne,
for tainting of ground, or a worſer ill turne:
Such peſtilent ſmell of a carrenly thing,
to cattell and people great perill may bring.

37 Thy meaſeled Bacon, Hog, Sow, or thy Bore,
ſhut up for to heale, for infecting thy ſtore:
Or kill it for Bacon, or ſouſe it to ſell,
for Flemming that loves it ſo daintily well.

38 with ſtraw wiſpe & peaſe-bolt, with ferne & the brake
for ſparing of fewell, ſome brew and doe bake:
And heateth their Copper, for ſeething of graines,
good ſervant rewarded, refuſeth no paines.

39 Good bread-corne & drinke-corne full xx. weeks kept
is better than new, that at harveſt is reapt:
But foiſty thy bread-corne, and bowdeaten malt,
for health or for profit find noyſome thou ſhalt.

40 By the end of October, goe gather up Sloes,
have thou in readineſſe plenty of thoſe:
And keepe them in bedſtraw, or ſtill in the bow,
to ſtay both the flix of thy ſelfe and thy Cow.

41 Sith water and plumpe therein plenty of ſloes,
mixe Chalke that is dryed in powder with thoſe:
which ſo if you give with the water and Chalke,
thou makeſt the lax frow thy Cow away walke.

42 Be ſure of Virgins (a gallon at the leaſt)
ſo good for the kitchin, ſo needfull for beaſt:
It helpeth thy cattell, ſo feeble and ſo faint,
if timely ſuch cattell, with it thou acquaint.

Thus endeth Octobers Husbandry.

Novembers

Reproduced from Thomas Tusser's "Five Hundred Points of Good Husbandry," London, 1638.

advocated enclosed fields or pastures whereby livestock was subject to control.

In 1557 Thomas Tusser was author of a small book entitled "A Hundred Good Pointes of Husbandrie." This has been rated by Donald McDonald,† "more as a series of good farming and domestic directions and axioms, than as a regular treatise upon agriculture."

In 1573 another little book by Tusser, entitled "Five hundreth pointes of good husbandry" was published. These two books were later brought out in revised editions. For example a copy published in 1638 in my possession, specifies on the title page that it is "Corrected, better ordered, and newly augmented to a fourth part more, with divers other lessons, as a dyet for the Farmer, of the properties of Windes, Plants, Hops, Hearbes, Bees, and approved Remedies for Sheepe and Cattell; with many other marter's both profitable, and not unpleasant to the Reader." These books are in poetical meter, set forth in old black-face type common three centuries ago. In this interesting form of expression Tusser for example writes of the care of farm animals as follows:

"Ewes yearely by twinning, rich masters doe make,
the lambe for such twinners, for breeders go take;
For twinnings be twiggers, increase for to bring,
though some for their twigging, *Peccavi* may sing."

Original copies of these publications of Tupper are real rarities, favorites of book collectors, and command a high price.

A reprint of the works of Thomas Tusser by Dorothy Hartley (London, no date), at its conclusion offers his epitaph, which is as follows:

"Here Thomas Tusser, clad in earth, doth lie,
who sometime made the Points of Husbandry;
By him then learn thou may'st—here learn we must,
when all is done, we sleep, and turn to dust;
And yet, through Christ, to heaven we hope to go,
Who reads his books, shall find his faith was so."

Fitzherbert and Tusser were the pioneer agricultural writers who gave attention to the merits of farm animals. In these later days of the sixteenth century a number of other writers appeared who were authors of books which contained comments on farm animals, though none of these deserve consideration here.

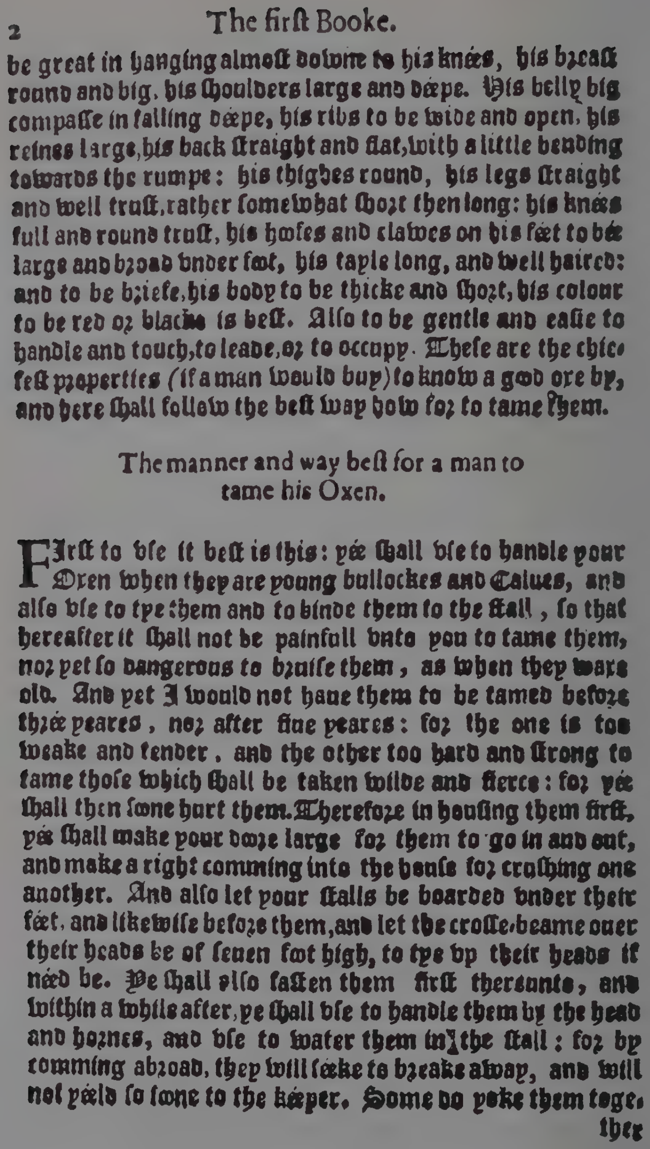
† Agricultural Writers from Sir Walter of Henley to Arthur Young—1200-1800, London, 1908, pp. 228, with many page illustrations.



be great in hanging almoſt downe to his knées, his breaſt round and big, his ſhoulders large and déepe. His belly big compaſſe in falling déepe, his ribs to be wide and open, his reines large, his back ſtraight and flat, with a little bending towards the rumpe: his thighes round, his legs ſtraight and well truſt, rather ſomewhat ſhort then long: his knées full and round truſt, his hoofes and clawes on his féet to bée large and broad vnder féet, his tayle long, and well haired: and to be briefe, his body to be thicke and ſhort, his colour to be red or blacke is beſt. Alſo to be gentle and eaſie to handle and touch, to leade, or to occupy. Theſe are the chiefeſt properties (if a man would buy) to know a good oxe by, and here ſhall follow the beſt way how for to tame them.

The manner and way beſt for a man to tame his Oxen.

FIrſt to vſe it beſt is this: yée ſhall vſe to handle your Oxen when they are young bullockes and Calues, and alſo vſe to tye them and to binde them to the ſtall, ſo that hereafter it ſhall not be painfull vnto you to tame them, nor yet ſo dangerous to bruiſe them, as when they ware old. And yet I would not haue them to be tamed before thrée yeares, nor after fiue yeares: for the one is too weake and tender, and the other too hard and ſtrong to tame thoſe which ſhall be taken wilde and fierce: for yée ſhall then ſoone hurt them. Therefore in houſing them firſt, yée ſhall make your doore large for them to go in and out, and make a right comming into the houſe for cruſhing one another. And alſo let your ſtalls be boarded vnder their féet, and likewiſe before them, and let the croſſe-beame ouer their heads be of ſeuen foot high, to tye vp their heads if néed be. Ye ſhall alſo faſten them firſt therevnto, and within a while after, ye ſhall vſe to handle them by the head and hornes, and vſe to water them in the ſtall: for by comming abroad, they will ſéeke to breake away, and will not yéeld ſo ſoone to the kéeper. Some do yoke them toge-
ther

Reproduced from "The Government of Cattell," by Leonard Mascal, London, 1633.

The first book exclusively devoted to livestock, was "gathered" by Leonard Mascall, upon "The Gouvernment of Cattell." The word cattle at this time, is generally used to relate to all kinds of farm livestock. Mascall is supposed to have been born about 1546, but the date is uncertain. He was the author in 1572 of "A booke of the Art and Manner how to graff and plant all sortes of Trees, how to set stones and sow Pepins, to make wilde trees to graff on, as also remedies and medicines, with other new practices." This, a translation from the French by the Abbey of St. Vincent, was published in many editions, and had a large sale for that day. Mascall also wrote on "The Husbandrye, Ordring and Government of Poultrie." The book on cattle was first published in 1596, and its contents were grouped in three books. "The first entreating of Oxen, Kine and Calves; and how to use Buls and other Cattell, to the yoake or sell. The second, discoursing of the Gouvernment of Horses, with approved Medicines against most diseases. The third, discouvering the ordering of Sheepe, Goates, Hogges and Dogges, with true Remedies to help the infirmities that befall any of them."

A 1633 and 7th edition of this book in my library occupies 309 pages. This volume and no doubt an earlier edition mainly deals with the diseases of animals and their treatment. The subject of breeds had not yet been introduced, though the evolution of some breeds was in process in English counties some 400 years ago.

In this book Mascall first discusses "what knowledge a man ought to have that wishest to buy and sell Oxen." He refers to the fact that beasts have many diversities, according to the countries in which bred, whether Asia, France, Spain, England, etc. He then describes the characteristics of a good ox as follows, which by the way is very similar to that of Columella, the noted Roman agricultural writer of the second century A. D. "He that will buy Oxen must buy young oxen, well quartered, having large and big members, with long horns, somewhat blacke, strong & big: his forehead broad, and his browes wrinkled: his eares rough within and hairy like velvet, his eyes great & large, his mouzell black, his nostrils crooked within, very open and wide, the chine of his necke long, thicke and straight, the dewappe or skinne that hangeth under his throat to be great in hanging almost downe to his knees, his breast round and big, his shoulders large and deep. His belly big compasse in falling deepe, his ribs to be wide and open, his reins large, his back straight and flat, with a little bending towards the rumpe: his thighes round, his legs straight and well trust, rather somewhat short then long: his knees full and round trust, his hoofes and clawes on his feet to bee large and broad underfeet, his tayle long, and well haired: and to be briefe, his body to be thicke and shorte, his colour to be red or blacke is best. Also to be gentle and easie to handle and touch, to leade or to occupy. These are the choicest properties (if a man would buy) to know a good oxe by, and here shall follow the best way how for to tame them."

This statement of what should be sought for in an ox, or steer, as set forth in English in 1596, now nearly 350 years ago, is the earliest on this subject, I have thus far discovered. In this case, it may be assumed that the word *reins* is synonomous with the word loins. Yet what a description of a beef animal, compared with that of today.

Many writers on agriculture offered their wares for public consumption in book form during the seventeenth century, but the subject of farm animals, aside from a discussion of diseases and their treatment, received slight attention. The horse was regarded as of first importance, with meat production decidedly secondary. Yet from the eleventh to the end of the seventeenth century, some remarkable developments had taken place in England. Many of the largest, most beautiful and dignified cathedrals of history, had been erected there, this in spite of the fact that the country was frequently at war with other nations. While the first census as to population was not taken until 1801, it is estimated* that in 1650 England and Wales contained a population of 5½ million, which in another century was probably increased to 6½. In 1558, Queen Elizabeth ascended the throne, where, as one of the greatest rulers of England she administered affairs until 1603. In 1688 came what was known as the glorious revolution, the final overthrow of royal despotism, the establishment of constitutional government, and the Bill of Rights—the great guarantee of English liberty. In 1693 the National Debt was started, there was a revolution in British finance, the Bank of England was founded in 1694, and the security of investments established. According to Lord Ernle† "the average dead weight of sheep and cattle in 1500 probably did not exceed 28 lbs. and 320 lbs. respectively. At the beginning of the seventeenth century the dead weight of the oxen and sheep supplied to the Prince of Wales household was no doubt exceptional; but the difference is considerable. 'An ox should weigh 600 lbs. the four quarters—a mutton should weigh 46 or 44 lbs.' "

---

* Enclyclopedia Americana, vol. 10, 1922, p. 356.

† English Farming Past and Present, London, 1922, p. 98.

The word breed has hardly found use until along in the seventeenth century, when Gervaise Markham, one of the most prolific of early English agricultural writers, in 1615 wrote:† "As touching the right Breed of Kine through our Nation, it generally affordeth very good ones, yet some countries (meaning counties) do far exceed other countries, as Cheshire, Lancashire, Yorkshire and Derbyshire, for Black Kine: Gloucestershire, Somersetshire and some parts of Wiltshire for red Kine, and Lincolnshire for pied Kine." Color and horns were two of the most discussed subjects regarding cattle at that time.

It is important to note here that along in the seventeenth and notably the eighteenth century, the introduction of livestock, and especially cattle, from the Continent of Europe, but more especially Holland, took place. Consequently, says Prof. James Wilson* "it may be doubted whether the idea that their livestock might be improved, ever took much hold of British farmers' minds before the arrival of the importations of cattle and other stock from Holland. At any rate it was not the overmastering idea it has since become. For one thing, they knew of nothing either very much better or very much worse than their own, unless perhaps, on the common frontiers of two races, say the English and the Celtic, or here and there in the North."

It will be appropriate now to introduce an important comment on this period quoted from Lord Ernle,‡ one of the eminent recent authorities on English agriculture. "The gigantic advance of agriculture to the nineteenth century develops into insignificance any previous rate of progress. Yet the change between 1700 and 1800 was astonishing. England not only produced food for a population that had doubled itself, as well as grain for treble the number of horses, but during the first part of the period became, as M. de Lavergne has said, the granary of Europe. Population before 1760 grew so slowly that the soil without any great increase in farming skill or in cultivated areas, produced a surplus. Under the spur of the bounty, land which had been converted to pasture was again plowed for corn, and proved by its yield that it had profited by the prolonged rest. The price of wheat, between the years 1713 and 1764, in spite of large exports, averaged 34s. 11d. ($8.70) per quarter; poor-rates fell below the level of the preceding century; real wages were higher than they had been since the reign of Henry VI (1421-'71). In England, at least, there was little civil war or tumult, no glut of the labor market, no sudden growth of an artisan class. The standard of living improved. Instead of the salted carcasses of half starved and aged oxen, fresh meat began to be eaten by the peasantry. Wheaten bread ceased to be a luxury of the wealthy, and, at the accession of George III (1761) had become the breadstuff of half the population. Politically and morally the period was corrupt and coarse; materially it was one of the Golden Ages of the peasant. The only drawbacks to the general prosperity of agriculture during the first half of the century were the visitations of the rot and of the cattle plague."

‡ English Farming Past and Present, (3d. ed.) London, 1922, pp. 148-9.

It was during the first half of the eighteenth century that Jethro Tull, born in 1674, became one of the foremost agricultural improvers, for he invented a drill of practical service, for the first time which deposited the seed in rows. He also invented various other agricultural implements, but the drill was what gave him the greatest distinction. In 1732 he was author of a dignified book.* The second edition, a copy of which is in my library, is of folio size and contains five beautiful full page engravings showing details of plows and drills. In this book of 278 pages, from page 205 to 274, he presents a "Supplement to the Essay on Horse-Hoing Husbandry containing Explanations and Additions both in Theory and Practice, wherein all the objections against that husbandry, which are come to the author's knowledge, are considered and answered," which might be regarded a remarkable procedure. Tull died in 1740, at Mt. Prosperous, in Berkshire, the most constructive student in agricultural progress in the history of England up to his time.

Attention may now be directed to a consideration of one, who in the estimation of many authorities, was one of the greatest, if not the greatest constructive breeder of farm animals in England prior to the 20th century. This was Robert Bakewell, born in 1725 on the farm known as Dishley in Loughborough, Leicestershire, England. At this time there were no standards of form with cattle in that country. "The qualities for which animals were valued," says Lord Ernle,† "were not propensity to fatten or early maturity, but their milking capacity or their power of draught. The pail and the plough set the standard; the butcher was ignored."

* Horse-Hoing Husbandry; Complete in Four Parts, or an Essay on the Principles of Tillage and Vegetation. London, 1733. A second edition, 1743.

† English Farming Past and Present, (3d. ed) 1922, p. 179.

Bakewell represents the first breeder of livestock in England who made a careful study of animal form, and then mated animals with emphasis on the value of blood lines and the reproduction of like qualities from parents. Mr. Bakewell was not gifted with the use of the pen, and so did not contribute much to the literature of livestock husbandry as practiced by him.

One must look to the report on "The Rural Economy of the Midland Counties; including the management of Livestock In Leicestershire and its environs," by Mr. William Marshall, for the most authentic information concerning the methods of Bakewell. This book published in two volumes in 1796, Volume I being devoted to Live Stock and consideration of Mr. Bakewell and his work, as well as the practice of breeders of the county in general. While Bakewell bred cart horses, Long horn cattle and what he termed New Leicestershire sheep, his more important efforts were with cattle and sheep.

Without going into much detail, Mr. Bakewell obtained a cow from a local breeder named Webster of Canley, said to have been, "during many years the leading breeder of the Midland Counties." This cow, named Comely, produced the bull calf, Twopenny, that later was highly valued as a sire. A son of his that lived to some twelve years of age, and named D, also sired cattle of distinct superiority, that made a great impress in his day on beef cattle breeding. The policy of Mr. Bakewell was to use his bulls on their dams and sisters, thus involving incestuous breeding. The bull D for example was sired by Twopenny, and out of a daughter and sister of the same bull.

Mr. Bakewell is credited with the following principles as guiding him in his breeding operations:

1st. *Beauty of form,* a principle adhered to especially at the beginning of improvement.

2d. *Utility of form,* "abstractedly considered as separate from the beauty of form."

3d. *Flesh,* or texture of muscular parts, long familiar to butchers and consumers, but not to breeders.

4th. *Fat,* which "engrosses the greatest share of attention, and which, above all others, is entitled to the *grazier's* attention." This involves the natural propensity to acquire a state of fatness.

In and in-breeding, one might very appropriately add to this list of principles, because as already said, he used it quite freely and was really the first person to adopt such a policy.

It is important to note here that the practice of leasing bulls originated in Leicestershire and chiefly with Mr. Bakewell, and was generally adopted. The bulls were sent out in April or the beginning of May, and were returned in August. The prices varied from ten to fifty or sixty pounds ($50. to $250. or $300.); but in one case a bull named Shakespeare, sired by old D., owned by a man named Fowler, was let at eighty guineas ($400.) the season.

Before concluding this sketch of the operations of Robert Bakewell, attention should be given to the following from the Gentleman's Magazine of London, in which was a special article on Mr. Bakewell and quoted by Youatt.* "The gentleness of the different breeds of cattle could not escape the attention of any observer. It seemed to run through them all. At an age when most of his brethren are either foaming or bellowing with rage and madness, old C, a bull, a son of the old parent Comely, had all the gentleness of a lamb, both in his look and action. He would lick the hand of his feeder, and if any one patted or scratched him he would bow himself down almost to his knees.

"The same writer describes Mr. Bakewell's servants, one of whom had been with him 20 years, and another 32, and another 40 years. He likewise gives a curious account of Mr. Bakewell's hall. The separate joints and points of each of the more celebrated of his cattle were preserved in pickle, or hung up side by side; showing the thickness of the flesh and external fat on each, and the smallness of the offal. There were also skeletons of the different breeds, that they might be compared with each other, and the comparative difference marked. Some joints of beef, the relics of old Comely, the mother of the stock, and who was slaughtered when her existance had become burdensome to her, were particularly remarked. The fat of the sirloin on the outside was four inches in thickness."

The type of cattle and sheep of the nineteenth and twentieth centuries, are of a smaller and improved form, yet representative more or less of the days of Bakewell, including the recognized beef or mutton producing breeds at their best, such as are standard representatives of today, and that possess loins that are wide, long and thick. Here are found the most highly valued cuts of the carcass. Yet if one studies the literature of meat production, he will be impressed with the fact that the word loin was not in common usage prior to Bakewell. The word and the special cut, are much more common in those meat producing countries, where the population is great, and the carcass is sold in the retail market in many separate pieces, with which the housewife is generally familiar. Thus one of an English community is logically more familiar with the various retail cuts than would be the housewife in an American community. However, due to the fine instruction now being given over America to audiences addressed by qualified educators from the great packing houses, in which carcasses are cut up and their parts plainly shown and discussed, great progress in this country is now taking place in meat comprehension.

HOGHTON TOWER
NEAR
BLACKBURN
IN
LANCASHIRE
FEBRUARY 21, 1676
BANQUET
FOR
HIS MAJESTY
KING CHARLES II

Students of the Department of Animal Husbandry dramatizing the Knighting of Sir Loin.

In the Knighting of Sir Loin at the Banquet in 1934 at Purdue University, a program was given as representing a Knighting at

Lancashire, England, on Feb. 21, 1676, in honor of His Majesty King Charles II. A poem of 26 lines by Robert Herrick set forth a bill of fare, and the back page quoted a discussion of table manners.

An invitation that I should attend your 1935 Knighting festivities, and be your speaker, suggested that I should be more familiar with what it was all about. I turned to my library, containing a large collection of English publications on agriculture and livestock husbandry, but in spite of my hunt I could find nothing satisfactory. Turning elsewhere, I naturally looked to the library of the Ohio State University, and here in the Oxford Dictionary of the English Language (1919, vol. IX Si-St) I found that for which I sought, as may be seen in the following three quotations from that great Dictionary.

The earliest record quoted by the dictionary* dates back to the first part of the 16th century in which it states that "a Sir-loyne of beef was set before Him (so knighted, saith tradition) by this King Henry VIII" (1491-1547).

King Charles II has been credited by various authorities with dubbing the knighthood on this piece of meat. His life covered the period 1630-1685, and the dictionary gives the following quotation as applied to him.† "*Sir-Loin of Beef*. This joint is said to own its name to King Charles the 2d, who, dining upon a loin of Beef said, "for its merit it should be knighted and henceforth called Sir-Loin."

The more complete explanation is quoted by Dean Swift.‡ This presumes to be a question as put by a Miss. "But, pray why is it called a Sir-Loyne?" Lord Sparkish replied, " 'Why, our King James 1st (1566-1625) being invited to Dinner by one of his Nobles, and seeing a large Loyn of Beef at his Table, he drew out his sword and knighted it.' "

In my own library among my treasures was a book by Thomas F. DeVoe, published in 1867 in New York City, with the title "*The Market Assistant*, containing a brief description of Every Article of Human Food sold in the Public Markets of the Cities of New York, Boston, Philadelphia and Brooklyn, including the various Domestic and Wild Animals, Poultry, Game, Fish, Vegetables, Fruits, etc. with many curious incidents and anecdotes." Under the very last features indicated in this extensive title I found yet another explanation of the knighting of Sir Loin. However, my

---

† Cook's Oracle, 1822, p. 163.

‡ For Light Conversation, vol. II, p. 121.

Knight here proved to be a Baron. Webster gives a satisfactory explanation of this, because in the item of cookery under the word Baron, it defines as "Two loins or sirloins not cut apart at the backbone; as a baron of beef." In view of the fact however, that a Baronet should always be addressed with *Sir* as a prefix to his given name only, I had located the correct title to the roast.

In a consideration of the part to be Knighted, DeVoe offers the following explanation.

"*The Hind-Quarters* are usually considered the choice quarters, as from them are cut or taken the large and famous "Baron of Beef," which the English hold in the highest estimation as the crowning dish for the Christmas dinner. This joint is seldom prepared in this country (America) but it is cut much like a saddle of mutton; that is, by leaving the two sirloins together, when being dressed, the hind-quarters of the animal are not separated, but cut so as to saddle or baronize them, by taking off the buttocks, rumps, sockets, tops of sirloins, and a part of the suet, which leaves almost a square looking piece, first known in England as the baron of beef; and this enormous piece is roasted whole."

Having thus set forth a new description as it were for this University, I will conclude this somewhat lengthy address with two interesting tales as presented by the author of *"The Market Assistant."*

"The principal dish, from time immemorial, for the Sovereigns of England at their Christmas dinner is the 'Royal Baron of Beef.' In an English print I read that 'it was this year (1854) cut from a fine Highland ox, fed by Prince Albert, and weighed 840 lbs. It was put down before an enormous fire on Saturday afternoon, and for 14 hours was watched and basted by relays of assistants under the head cook, after which it was trimmed and decorated, with holly and mistletoe apparently sprouting from the outside fat of the meat.' "

In an interesting publication by Armour and Company entitled "King Beef," of which my old friend Robert C. M. Auld is author,* in referring to the baron of beef, he said: "It was the masterpiece of all baronial feasts on high occasions, and its maintenance at the Christmas board of the present royal family of Britain is a tradition. The baron of beef which was served at Queen Victoria's Christmas table in 1867, was from Wm. McCombie's famous champion Angus bullock of that year, Black Prince. He offered the entire animal to Her Majesty, which she declined, but she was 'graciously pleased to accept the baron,' thus making it royal."

---

* Monthly letter to Animal Husbandmen, vol. XII, No. 9, Dec. 1931, p. 8.

"I am also much indebted to Charles H. Webb, Esq., the Almoner of St. George Society," again quoting Mr. DeVoe, "who informs me that this Society has had several barons of beef served up at their anniversary dinners, which were principally prepared by Mr. and Mrs. William Niblo. The following incident will show one of the mistakes which occurred with perhaps the largest baron of beef ever prepared for, or attempted to be roasted in New York, or elsewhere. This, no doubt, occurred from the anxiety of Mrs. Niblo to outdo all former efforts of giving this choice piece in the greatest perfection. She gave the order and the instructions to Mr. Andrew C. Wheeler (butcher, No. 19 Fulton Market) that it should be the *largest* and *finest* that he could procure. It was taken from a very choice animal, and, when trimmed, weighed some 280 lbs., then sent to Niblo—who then kept his famous garden and hotel corner of Broadway and Prince St.—the day before the grand dinner of the St. George Society was to take place. The same night, late, Mrs. Niblo was about to put it down to roast. She found it so large and unwieldly that she could not spit it, let alone roast it; so, about midnight she sent for Mr. Wheeler, who came and after cutting some 100 lbs. or more from it, they were enabled to get it spitted, and near enough to the fire to commence this great roast for the next afternoon's dinner. They had, however, almost given it up in despair before they succeeded; but it was said that it was superbly cooked and served, as everything else was with which Mrs. Niblo had to do."

In conclusion, no matter when or where Sir-Loin was first Knighted, one may be sure that no better beef is available for this great honor than such as the British or Yankee product of today, with Purdue University exemplifying the best.

Come, sons of summer, by whose toil,
We are the lords of wine and oil;
By whose tough labours and rough hands,
We rip up first, then reap our lands.
Crowned with the ears of corn, now come,
And to the pipe sing harvest home.
Come forth, my lord, and see the cart
Dressed up with all the country art. . . .
Well on, brave boys, to your lord's hearth,
Glitt'ring with fire, where, for your mirth,
Ye shall see first the large and chief
Foundation of your feast, fat beef;
With upper stories, mutton, veal,
And bacon which makes full the meal
With several dishes standing by
As here a custard, there a pie,
And here all-tempting frumentry.
And for to make the merry cheer,
If smirking wine be wanting here,
There's that which drowns all care, stout beer,
Which freely drink to your lord's health,
Then to the plough (the commonwealth)
Next to your flails, your fans, your vats,
Then to the maids with wheaten hats;
To the rough sickle, and crook'd scythe,
Drink, frolic, boys, till all be blythe.

—Robert Herrick—(1591-1674).

UNIVERSITY OF ARIZONA
LIBRARY

Circular No. 210 April, 1935

COMMERCIAL FEEDING STUFFS

UNIVERSITY OF ARIZONA
LIBRARY

Properly Tagged Feed Combined with Inspection and Analysis Provides Protection to Purchasers of Commercial Feeding Stuffs

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

This circular contains a condensed report of commercial feed inspection in Indiana for the year 1934 and includes additional information pertaining to the Indiana Feeding Stuffs Law and to the composition of feeding stuffs.

Table 1 shows the estimated tonnage based on the sale of inspection tags and the retail value of each class of feed sold in Indiana during the year 1934. It is estimated that 354,565 tons of commercial feeding stuffs were sold at a retail value of $13,088,287.

Table 2 gives the estimated annual total tonnage and expenditures for commercial feeding stuffs since 1911.

Table 3 shows the shipments withdrawn from sale and the reasons for taking such action.

Table 4 states the names and addresses of the manufacturers whose feeds were sampled and analyzed in 1934 and the number of samples passed and not passed. Of the 2,659 samples collected 407 were found to be incorrectly guaranteed and 286 were classed as being seriously deficient or misbranded.

Suggestions are given to manufacturers, dealers and purchasers of feed which if followed should be valuable to all concerned.

Table 5 gives the calcium and phosphorus content of feeding stuffs.

Table 6 contains the analyses of cereals and by-products for formulating guarantees.

Definitions of the various classes of feeding stuffs and explanation of the terms used in the analysis of them are given.

COMMERCIAL FEEDING STUFFS

H. R. KRAYBILL, *State Chemist*

P. B. CURTIS, *Associate Chemist* O. S. ROBERTS, *Chief Inspector*
Assistant Chemists, C. C. YUND, G. E. HALLIDAY, D. M. DOTY
Inspectors, C. M. COHEE, J. W. JACKMAN

The Indiana Feeding Stuffs Law is primarily a labeling law and imposes certain specific duties upon the manufacturers of commercial feeding stuffs. It requires the manufacturer to label each sack, package or container of commercial feed sold or offered for sale in Indiana with an Official Indiana State tag showing the minimum percentage guarantees for crude protein and crude fat, a maximum percentage guarantee for crude fiber and the specific name of each ingredient used in preparing the feed. Before such tags or labels can be issued it is necessary to register each brand of feed on a certificate furnished by the State Chemist. There is no registration fee but a minimum order for Indiana tags of $5.00 must accompany each certificate of registration. Mineral feeds containing no organic ingredient do not require the usual chemical feed guarantee but do require a declaration of each ingredient contained therein and minimum percentages of lime (CaO), phosphoric acid (P_2O_5), iodine (I) and the maximum percentage of salt (NaCl).

Amendment of Feeding Stuffs Law

The Indiana Feeding Stuffs Law as amended in 1933 permits the manufacturer or agent desiring to sell any concentrated commercial feeding stuff in packages or containers of five pounds or less to register such feeding stuff under an annual registration fee of $20.00. If this method of registration is chosen it is unnecessary for the manufacturer to attach an Indiana State label to each container of five pounds or less but it is necessary that the same information, as required on the Indiana tag, be stated on the private label or wrapper of the container. This amendment is of special interest to the Dog Food Industry which has developed so rapidly during the last few years. Copies of this amendment together with the law may be secured by making application to the State Chemist.

Estimated Sales of Commercial Feeding Stuffs in 1934

In order to enforce this law Inspectors of the State Chemist Department are constantly in the field inspecting commercial feeding stuffs in feed mills, mixing plants, cars, stores, and on the farm. Inspection samples of the different lots of feed are taken with specially designed samplers so as to secure a representative sample from each lot and these samples are then forwarded to the laboratory of the State Chemist where they are analyzed. During the year 1934, 2,659 samples were collected in all parts of the state. One inspection sample was secured from approximately each 133 tons of commercial feed sold in Indiana. This is computed from the estimated tonnage shown in Table 1, entitled "Estimated Sales of Commercial Feeding Stuffs in Indiana." Based on the sale of official state tags it is estimated that 354,565 tons of commercial feed with a retail value of $13,088,287 were sold in Indiana during the year 1934. Compared with the sales of 1933 there was an increase of 10 per cent in tonnage and a corresponding increase of 26 per cent in expenditures. The principal increases in tonnage were for hominy feed, poultry mash and cattle and dairy feeds while the principal decreases were for cottonseed meal and milk products.

From Table 2 it may be seen that the total tonnage sold in 1934 was higher than in any of the three preceding years.

Table 1.—Estimated Sales of Commercial Feeding Stuffs in Indiana

Kind of Feed	Estimated Tons			Estimated Retail Values, Dollars	
	1932	1933	1934	1933	1934
Alfalfa meal and leaf meal	2,906	3,125	3,313	$89,688	$108,666
Animal by-products (tankage, meat scraps, etc.)	35,656	38,531	39,313	1,392,896	1,486,031

Estimated sales, tons	498,887	512,096	322,125	244,909	322,318	354,565
Estimated retail value, dollars	$26,491,777	$24,293,652	$11,939,153	$6,853,043	$10,373,772	$13,088,287

Results of Inspection

All of the 2,659 samples were examined microscopically and 2,393 of them were analyzed chemically for moisture, crude protein, crude fat, crude fiber and ash content. Forty-eight samples of mineral feed were analyzed for lime (CaO), phosphoric acid (P_2O_5), iodine (I) and salt (NaCl) content.

Of the 2,659 samples examined, 407 of them were found to be technically misbranded while only 286 of them were found to be seriously deficient or misbranded. This latter group of samples representing 10.8% of the total samples are listed in Table 4 under the heading of "Number of Samples Not Passed."

Refunds

Shipments or batches of feed found to be seriously deficient were removed from sale immediately and the manufacturers were required to replace or rebuild such deficient lots to meet their guarantees or relabel them with correct guarantees. Refunds totaling $824.76 were made to dealers and consumers by 53 different feed manufacturers on 90 deficient lots of feed. Most of the refunds were made on shipments of protein deficient tankages and meat and bone scraps.

All refunds are required to be distributed to the consumers wherever possible and receipts for same must be filed with the State Chemist. In case there are no records as to the consumers the refunds may be turned over to a local charitable organization in the community where the feed was sold. In any case receipts must be secured and filed with the State Chemist.

The payment of a refund by the manufacturer to the consumer does not remove the violation but it does indicate good intentions on the part of the manufacturer and shows his willingness to do what he can to correct the violation. However, the payment of the refund does not nullify the right of anyone in the state to call a deficiency of analysis to the attention of the prosecuting attorney.

The most frequent violation of the Indiana Feeding Stuffs Law is in the matter of non-tagging (Table 3). Of the 553.7 tons of commercial feed withdrawn from sale 427.1 tons were removed because of the lack of Indiana State tags. Proper tagging of feeding stuffs cannot be emphasized too strongly. Neglect on the part of the manufacturer, distributor or dealer in attaching the official tag to each bag of feed may lead to serious violations of the Indiana Feeding Stuffs Law. On conviction the penalty of such violations is fifty dollars for the first offense and one hundred dollars for each subsequent offense.

Misbranding of feeding stuffs, especially poultry mashes, occurs quite often. Manufacturers incorporating cod liver oil in their mashes should bear in mind that such mashes require separate registrations from those of plain mashes. The Official Indiana State tag must state cod liver oil as an ingredient if it is added.

Table 3.—Withdrawals From Sale

Number of Shipments Withdrawn From Sale	Number of Manufacturers Represented	Reasons for Withdrawal From Sale	Amount Withdrawn Tons
186	129	Not tagged	427.1
40	35	Misbranded	21.8
30	21	Deficient in crude protein	73.0
12	5	Deficient in crude protein and excess crude fiber	14.8
8	6	Mutilated tags	3.0
4	1	Short weight	13.2
1	1	Deficient in iodine and excess salt	0.6
1	1	Deficient bone phosphate of lime	0.2
282	199	Totals	553.7

Table 4 gives the standing of the various feed manufacturers whose feeds were inspected during the year 1934. This summary of feed inspection may be of considerable value to purchasers of commercial feeds in that it shows just how careful the different manufacturers were in maintaining their guarantees and also in tagging their feeds.

Table 4.—Summary of Feed Inspection January 1, 1934, to December 31, 1934

Attention Manufacturers, Dealers and Consumers!

The Official State tag required by the Indiana Feed Law bears the facsimile signature of the State Chemist and states the manufacturer's guarantee. Manufacturers and dealers should not neglect to attach these Official Indiana tags to each and every bag of feed sold or offered for sale in Indiana.

Batch-mixing is permitted without registering and tagging of the final product, only when the purchaser or his agent actually comes to the mixing plant, makes a bona fide purchase of properly tagged ingredients, sees them before the mixing is done, and also assures himself that they are mixed according to the formula furnished. Unless the above conditions are fulfilled, all feed mixed according to formulas submitted must be registered for sale in Indiana and properly tagged with Official Indiana State tags.

Feed manufacturers when packing feeding stuffs in printed second-hand bags are requested to turn the bags inside out so that the original printing or stenciling will not be exposed.

Feed manufacturers when registering commercial feeding stuffs are requested to follow the following resolutions which have been adopted by the Association of American Feed Control Officials:

"Resolved, That this Association go on record as condemning the use of the word 'vitamin' in a brand name, and as opposing the acceptance of registration of feeds with this word in the brand name. (Adopted 1929.)"

"Resolved, That this Association go on record as condemning the use of any contraction of the word 'vitamin,' or any word suggesting vitamin in a brand name, and as opposing the acceptance of registrations of feeds under names which are in conflict with this resolution. (Adopted 1932.)"

For the benefit of manufacturers of mineral feeds and those interested in maintaining a definite calcium and phosphorus ratio in their feeds, Table 5 is again presented. The percentages are stated not only in terms of calcium and phosphorus, but also in terms of lime (CaO) and phosphoric acid (P_2O_5).

Table 5.—Calcium and Phosphorus Content of Feeding Stuffs

MATERIAL	Calcium (Ca)%	Lime (CaO)%	Phosphorus (P)%	Phosphoric Acid (P_2O_5)%
Alfalfa meal	1.22	1.70	0.23	0.53
Brewers' dried grains	0.16	0.22	0.45	1.03
Buttermilk dried	2.43	3.40	0.96	2.20
Corn	0.01	0.02	0.28	0.65
Corn gluten feed	0.25	0.35	0.27	0.62
Cottonseed meal	0.26	0.37	1.26	2.89
Cowpeas	0.10	0.14	0.45	1.02
Distillers' grain corn	0.04	0.06	0.29	0.67
Fish meal (20.0% ash)	6.65	9.30	3.50	8.00
Hominy feed	0.03	0.04	0.45	1.03
Linseed oil meal	0.36	0.51	0.72	1.65
Malt sprouts	0.15	0.21	0.70	1.61
Meat and bone scraps (30.0% ash)	11.18	15.64	5.06	11.58
Meat scraps (22.0% ash)	8.19	11.46	3.71	8.49
Oats	0.10	0.14	0.37	0.85
Skimmed milk dried	1.29	1.80	0.96	2.20
Soybeans	0.21	0.29	0.60	1.37
Soybean oil meal	0.27	0.38	0.76	1.75
Tankage digester (20.0% ash)	7.10	9.93	3.21	7.35
Wheat	0.04	0.06	0.38	0.86
Wheat bran	0.09	0.13	1.20	2.74
Wheat middlings	0.07	0.10	0.90	2.06
Wheat red dog flour	0.12	0.17	0.85	1.95
Bone meal steamed	28.60	40.00	13.11	30.00
Bone black	28.60	40.00	13.11	30.00
Dicalcium phosphate	22.88	32.00	17.48	40.00
Rock phosphate	28.60	40.00	13.11	30.00
Super phosphate 16%	17.16	24.00	6.99	16.00
Super phosphate 20%	17.88	25.00	8.74	20.00
Phosphatic limestone	35.75	50.00	4.37	10.00
Limestone (95% calcium carbonate)	37.90	53.00	....	....
Oyster shells (95% calcium carbonate)	37.90	53.00	....	....
Wood ashes	21.45	30.00	....	....
Gypsum	25.03	35.00	....	....

Table 6, entitled "Analyses of Cereals and By-Products," may also be helpful to manufacturers in calculating safe guarantees for their feed formulas. Although the percentages of Ash and Nitrogen Free Extract are not required on the official tag, they are included in Table 6 this year in response to numerous requests.

Table 6.—Analyses of Cereals and By-Products

MATERIAL	POUNDS IN ONE HUNDRED				
	Crude Protein	Crude Fat	Crude Fiber	Ash	Nitrogen Free Extract
Alfalfa leaf meal	20.0	2.5	18.0	12.0	40.0
Alfalfa meal	13.0	1.5	33.0	9.0	35.0
Alfalfa stem meal	9.0	0.8	40.0	7.5	32.0
Barley	11.0	1.8	6.0	2.5	69.0
Beet pulp	8.5	0.9	19.0	3.5	59.0
Blood meal	80.0	0.5	....	3.3	3.0
Bone meal raw	23.0	3.0	2.0	60.0	3.0
Bone meal steamed	6.0	0.5	2.0	80.0	2.0
Brewers dried grains	26.0	6.0	15.0	3.8	41.0
Buckwheat	10.5	2.5	10.0	2.0	62.0
Buckwheat middlings	28.8	7.3	6.0	4.8	43.0
Buckwheat mixed feed	13.0	3.2	28.5	3.2	40.0
Buttermilk condensed	10.0	2.0	....	3.7	12.0
Buttermilk dried	32.0	5.0	....	12.0	43.0
Cane seed	9.0	2.5	2.5	2.0	71.0
Charcoal	....	....	80.0	3.5	....
Cocoanut oil meal	22.0	8.0	9.0	5.5	45.0
Cod liver oil	....	100.0	....	....	....
Corn	9.5	4.0	2.0	1.5	72.0
Corn ear	8.0	3.5	8.0	1.5	67.0
Corn cob	2.0	0.5	32.0	1.5	54.0

Table 6.—Continued

MATERIAL	POUNDS IN ONE HUNDRED				
	Crude Protein	Crude Fat	Crude Fiber	Ash	Nitrogen Free Extract
Corn bran	7.0	2.5	10.0	2.5	67.0
Corn feed meal	9.0	3.5	1.5	1.0	74.0

It is important that all of the terms used in the analysis of feeding stuffs and also the definitions of the various classes of feeding stuffs be thoroughly understood by the feed trade; therefore, this information is given in detail on the remaining pages of this circular.

Explanation of Terms Used in the Analysis of Feeding Stuffs

Moisture is the varying quantity of water occurring in feeding stuffs which can be driven off by heat at the temperature of boiling water. The amount of water present varies with the temperature, moisture content of the air, processes of manufacture and the character of the substance. In most concentrates this value ranges from 5 to 15 per cent.

Crude Fat consists mainly of fats and oils with small amounts of waxes, resins, coloring matter and similar substances, dissolved from feeding stuffs by dry ether. In calculating the heat and energy value of a feed, the fat is considered 2.25 times greater than that of either carbohydrates or protein.

Crude Protein is the term applied to the nitrogenous constituents of a feeding stuff. It is obtained by multiplying the total nitrogen by 6.25. Protein is the most important as well as the most costly constituent in a feed. Plants have the power of building up protein from the inorganic elements of the soil and air while animals must secure their protein from the plants or other animals. The plant proteins contain varying amounts of the essential amino acids; therefore, it is necessary to carefully select a variety of feeds which will furnish the essential amino acids economically.

Crude Fiber is the woody portion of a feeding stuff, for the most part cellulose, and is insoluble in dilute acids and alkalis. Most of the common seeds and grains contain very little fiber while the hulls, husks and stems are high in this constituent. In poultry and swine, crude fiber, when present in considerable quantities, exerts a retarding influence on the digestion of nutrients present.

Ash, the mineral matter of plants, is the residue left after burning a feeding stuff at low redness. It consists chiefly of the phosphates, sulphates, chlorides and carbonates of sodium, potassium, calcium and magnesium. The calcium and phosphorus are absolutely essential for the proper nutrition of the animal.

Nitrogen Free Extract consists of sugars, starches, pentoses, non-nitrogenous organic acids, etc., and is determined by subtracting the sum of moisture, crude fat, crude protein, crude fiber and ash from 100.

Carbohydrates is the sum of the crude fiber and nitrogen-free extract.

DEFINITIONS OF FEEDING STUFFS*

Alfalfa Products

1. **Chopped Alfalfa** is the entire alfalfa hay, chopped and not ground finely enough to become a meal. It must not contain an admixture of alfalfa straw or other foreign material. (Adopted prior to 1928.)

2. **Alfalfa Meal** is the product obtained from the grinding of the entire alfalfa hay, without the addition of any alfalfa stems, alfalfa straw or foreign material, or the abstraction of leaves. It must be reasonably free from other crop plants and weeds, and must not contain more than 33 per cent of crude fiber. (Adopted 1928.)

3. **Alfalfa Leaf Meal** is the ground product consisting chiefly of leafy materials separated from alfalfa hay. It must be reasonably free from other crop plants and weeds and must not contain more than 18 per cent of crude fiber. (Adopted 1928.)

4. **Alfalfa Stem Meal** is the ground product remaining after the separation of the leafy material from alfalfa hay or meal. It must be reasonably free from other crop plants and weeds. (Adopted 1928.)

Animal Products

5. **Blood Meal** is ground, dried blood. (Adopted 1926.)

6. **Blood Flour** is dried blood, prepared by special processes and reduced to a fine powder. (Adopted prior to 1928.)

7. **Digester Tankage, Meat Meal Tankage or Feeding Tankage** is the residue from animal tissues exclusive of hoof, horn, manure and stomach

---

* These definitions have been adopted by the Association of American Feed Control Officials.

contents, except in such traces as might occur unavoidably in good factory practice, especially prepared for feeding purposes by tanking under live steam or by dry rendering or a mixture of the products made suitable by drying and grinding. It must not contain more than 10 per cent of phosphoric acid (expressed as P_2O_5). If it bears a name descriptive of its kind, composition or origin, the material must correspond thereto. (Adopted 1928; amended 1933.)

8. **Digester Tankage with Bone, Meat and Bone Meal Digester Tankage, Meat and Bone Meal Tankage, or Feeding Tankage with Bone** is the residue from animal tissues, exclusive of hoof, horn, manure and stomach contents, except in such traces as might occur unavoidably in good factory practice, especially prepared for feeding purposes by tanking under live steam or by dry rendering or a mixture of the products made suitable by drying and grinding, and containing more than 10 per cent of phosphoric acid (expressed as P_2O_5). If it bears a name descriptive of its kind, composition or origin, it must correspond thereto. Adopted 1928; amended 1933.)

9. **Meat Scraps** is the ground, dry-rendered residue from animal tissues, exclusive of hoof, horn, manure and stomach contents, except in such traces as might occur unavoidably in good factory practice. When this product contains more than 10 per cent of phosphoric acid (expressed as P_2O_5), it shall be designated Meat and Bone Scrap. If it bears a name descriptive of its kind, composition or origin, it must correspond thereto. (Adopted 1928.)

10. **Raw Bone Meal** is the dried, ground product suitable for animal feeding, obtained by cooking in water at atmospheric pressure, undecomposed bone, just enough to remove excess fat and meat. It must not contain less than 23 per cent of protein. (Adopted 1929.)

11. **Steamed Bone Meal** is the dried, ground product suitable for animal feeding obtained by cooking bones with steam under pressure. (Adopted 1929.)

12. **Special Steamed Bone Meal** is the dried, ground product suitable for animal feeding, obtained by cooking dried bone after the removal of grease and meat fiber with steam under pressure in the process of obtaining gelatine or glue. (Adopted 1929.)

Apple Products

13. **Dried Apple Pomace** is the sound, dried residue obtained by the removal of cider from apples. (Adopted 1929.)

14. **Dried Apple Pectin Pulp** is the sound, dried residue obtained by the removal of pectin from apple products. (Adopted 1929.)

Barley Products

15. **Barley Hulls** is the product consisting of the outer coverings of the barley. (Adopted prior to 1928.)

16. **Barley Feed** is the entire by-product resulting from the manufacture of pearl barley from clean barley. (Adopted prior to 1928.)

17. **Barley Mixed Feed** is the entire offal from the milling of barley flour from clean barley and is composed of barley hulls and barley middlings. (Adopted prior to 1928.)

18. **Ground Barley** is the entire product obtained by grinding clean, sound barley containing not less than 90 per cent of pure barley and not more than 10 per cent of other grains, weed seeds and other foreign material and not more than 6 per cent of crude fiber; provided that no portion of this stated 10 per cent of other grains, weed seeds or other foreign material shall be intentionally added. (Adopted prior to 1928.)

19. **Mixed Feed Barley** is the entire product obtained by grinding coun-

try-run barley, containing not less than 75 per cent of pure barley and not more than 25 per cent of other grains, weed seeds and other foreign material; provided that no portion of this stated 25 per cent of other grains, weed seeds or foreign material shall be intentionally added. The ingredients must be stated as barley, other grains, weed seeds and foreign material. (Adopted prior to 1928.)

Beet Products

20. **Dried Beet Pulp** is the dried residue from sugar beets which have been cleaned and freed from crowns, leaves and sand, and from which the sugar has been extracted. (Adopted prior to 1928.)

Brewers' and Distillers' Products

21. **Brewers' Dried Grains** is the dried residue obtained in the manufacture of beer. (Adopted prior to 1928.)

22. **Distillers' Corn Dried Grains or Distillers' Rye Dried Grains** is the dried residue obtained in the manufacture of alcohol and distilled liquors. The product must bear the designation indicating the cereal predominating. (Adopted prior to 1928.)

23. **Distillers' Corn Solubles** is a by-product from the manufacture of alcohol from corn solids obtained by the evaporation of the mash liquor after the removal of the alcohol and wet grains. (Adopted prior to 1928.)

24. **Distillers' Rye Solubles** is a by-product from the manufacture of alcohol from rye solids, obtained by the evaporation of mash liquor after the removal of the alcohol and wet grains. (Adopted prior to 1928.)

25. **Distillers' Corn and Rye Solubles** is a by-product from the manufacture of alcohol from corn and rye solids, obtained by the evaporation of mash liquor after the removal of the alcohol and wet grains. (Adopted prior to 1928.)

26. **Malt Sprouts** are the sprouts of the barley grain obtained from malted barley. Sprouts derived from any other malted cereal must be designated by the name of that cereal. (Adopted prior to 1928.)

27. **Yeast Dried Grains or Vinegar Dried Grains** is the properly dried residue from the mixture of cereals, malt and malt sprouts (sometimes cottonseed meal) obtained in the manufacture of yeast or vinegar, and consists of corn or corn and rye from which most of the starch has been extracted, together with malt added during the manufacturing process to change the starch to sugars, and malt sprouts (sometimes cottonseed meal) added during the manufacturing process to aid in filtering the residue from the wort and to serve as a source of food supply for the yeast. (Adopted prior to 1928.)

Buckwheat Products

28. **Buckwheat Shorts or Buckwheat Middlings** are the portions of the buckwheat grain immediately inside the hull secured after separation from the flour. (Adopted prior to 1928.)

Chop

29. **Chop** is a ground or chopped feed composed of one or more different cereals or by-products thereof. If it bears a name descriptive of the kind of cereals, it must be made exclusively of the entire grains of those cereals. (Adopted prior to 1928.)

Cocoanut Products

30. **....Per Cent Protein Cocoanut Oil Meal or....Per Cent Protein Copra Oil Meal** is the ground residue from the extraction of part of the oil from the dried meat of the cocoanut. (Adopted prior to 1928.)

Corn Products

31. **Corn Meal** (Feeding) is finely ground, unbolted corn. (Adopted prior to 1928.)

32. **Corn Bran** is the outer coating of the corn kernel, with little or none of the starchy part or germ. (Adopted 1931.)

33. **Corn Feed Meal** is the fine siftings obtained in the manufacture of screened corn chop, screened ground corn or screened cracked corn, with or without its aspiration products added. (Adopted 1931.)

34. **Corn Chop, Ground Corn or Cracked Corn** is the entire product made by grinding, cutting or chopping the grains of sound Indian corn, and may be fine, medium or coarse, and must not contain more than 4 per cent of foreign material. (Adopted 1931.)

35. **Screened Corn Chop, Screened Ground Corn, or Screened Cracked Corn** is the coarse portion of corn chop, ground corn or cracked corn from which most of the fine particles have been removed, and must not contain more than 4 per cent of foreign material. (Adopted 1931.)

36. **Corn Grits or Hominy Grits** is the product consisting of the fine or medium sized, hard flinty portions of sound Indian corn containing little or none of the bran or germ. (Adopted 1931.)

37. **Ear Corn Chops** is corn and cob chopped, without the husk, with no greater proportion of cob than occurs in the ear corn in its natural state. (Adopted prior to 1928.)

38. **Corn Gluten Meal** is that part of commercial shelled corn that remains after the separation of the larger part of the starch, the germ and the bran, by the processes employed in the manufacture of corn starch. It may or may not contain corn solubles. (Adopted prior to 1928.)

39. **Corn Gluten Feed** is that part of commercial shelled corn that remains after the separation of the larger part of the starch and the germs by the processes employed in the manufacture of corn starch. It may or may not contain corn solubles. (Adopted prior to 1928.)

40. **Maltose Process Corn Gluten Feed** is the dried residue from degermed corn, after removal of the starch in the manufacture of malt syrup. (Adopted prior to 1928.)

41. **Hominy Feed, Hominy Meal or Hominy Chop** is the kiln-dried mixture of the mill-run bran coating, the mill-run germ, with or without a partial extraction of the oil, and a part of the starchy portion of the white corn kernel obtained in the manufacture of hominy, hominy grits, and cornmeal by the degerming process. (Adopted prior to 1928.)

42. **Yellow Hominy Feed, Yellow Hominy Meal or Yellow Hominy Chop** is the kiln-dried mixture of the mill-run bran coating, the mill-run germ, with or without a partial extraction of the oil, and a part of the starchy portion of the yellow corn kernel obtained in the manufacture of yellow hominy grits and yellow corn meal by the degerming process. (Adopted prior to 1928.)

43. **Corn Oil Cake** consists of the corn germ from which part of the oil has been pressed and is the product obtained in the wet milling process of manufacture of corn starch, corn syrup, and other corn products. (Adopted prior to 1928.)

44. **Corn Oil Meal** is ground corn oil cake. (Adopted prior to 1928.)

45. **Corn Germ Cake** consists of corn germ with other parts of the corn kernel from which part of the oil has been pressed, and is the product obtained in the dry milling process of manufacture of corn meal, corn grits, hominy feed, and other corn products. (Adopted prior to 1928.)

46. **Corn Germ Meal** is ground corn germ cake. (Adopted prior to 1928.)

47. **Corn Screenings** is the product consisting of the small light grains of

corn, parts of grains of corn and/or other cereals, and other materials having feeding value, obtained by screening shelled corn, excluding sand, dirt and other similar inert materials. (Adopted 1931.)

Cottonseed Products

48. **Cottonseed Meal** is a product of the cottonseed only, composed principally of the kernel with such portion of the hull as is necessary in the manufacture of oil; provided that nothing shall be recognized as cottonseed mea that does not conform to the foregoing definition and that does not contain at least 36 per cent of protein. Cottonseed meal shall be graded and classed as follows: (Adopted prior to 1928.)

49.....**Per Cent Protein Cottonseed Meal, Prime Quality.** Cottonseed meal prime quality, must be finely ground, not necessarily bolted, of sweet odor reasonably bright in color, yellowish, not brown or reddish, free from excessive lint, and shall contain not less than 36 per cent of protein. It must be designated and sold according to its protein content. Cottonseed meal with 36 per cent of protein must be termed "36 per cent Protein Cottonseed Meal, Prime Quality," and higher grades similarly designated (as "43 per cent Protein Cottonseed Meal, Prime Quality"), etc. (Adopted prior to 1928.)

50.....**Per Cent Protein Cottonseed Meal, Off Quality.** Cottonseed meal not fulfilling the above requirement as to color, odor and texture must be graded "36 per cent Protein Cottonseed Meal, Off Quality," and higher grades similarly designated. (Adopted prior to 1928.)

51. **Cottonseed Feed** is a mixture of cottonseed meal and cottonseed hulls containing less than 36 per cent of protein. (Adopted prior to 1928.)

52.....**Per Cent Protein Whole Pressed Cottonseed**, Prime Quality, is the product resulting from subjecting the whole, sound, mature, clean undecorticated cottonseed to pressure for the extraction of oil, and includes the entire cottonseed less the oil extracted and the lint removed. It must be dsignated and sold according to its protein content. (Adopted 1932.)

53.....**Per Cent Protein Ground Whole Pressed Cottonseed,** Prime Quality is whole pressed cottonseed, ground. It must be designated and sold according to its protein content. (Adopted 1932.)

Garbage

54. **Processed Garbage** is composed of dried animal and vegetable waste from garbage collected sufficiently often that harmful decomposition has not set in, and separated from material such as crockery and glass. Its odor must not be suggestive of the presence of decomposition and it must contain less than one per cent of glass. None of it shall contain knife-like or needle-like particles, and the maximum percentage of glass should be stated on the label when present in excess of one-fifth of one per cent. (Adopted prior to 1928.)

Ivory Nut Products

55. **Ivory Nut Meal** is the ground waste material resulting from the manufacture of buttons and similar articles from the vegetable ivory nut. (Adopted prior to 1928.)

Linseed and Flax Products

56.....**Per Cent Protein Linseed Cake or Linseed Meal** is the product obtained in the removal of the oil from flaxseed; provided that the final product contains less than 6 per cent of weed seeds and other foreign materials; and provided, further, that no portion of the stated 6 per cent of weed seeds and other foreign materials shall be deliberately added. It shall not contain more than 0.5 per cent of acid insoluble ash. (Adopted 1933.)

57.....**Per Cent Protein Old Process Oil Meal or....Per Cent Protein Old**

Process Linseed Meal is oil meal as defined below, produced by crushing, cooking and hydraulic pressure. (Adopted prior to 1928.)

58.....**Per Cent Protein New Process Oil Meal or....Per Cent Protein New Process Linseed Meal** is oil meal as defined below, produced by crushing, heating and the use of solvents. (Adopted prior to 1928.)

59. **Flax Plant By-Product** is that portion of the flax plant remaining after the separation of the seed, the bast fibre and a portion of the shives, and consists of flax shives, flax pods, broken and immature flax seeds, and the cortical tissues of the stem. (Adopted prior to 1928.)

60. **Ground Flaxseed or Flaxseed Meal** is the product obtained by grinding flaxseed which has been screened and cleaned of weed seeds and other foreign materials by the most improved commercial process; the final product must contain less than 4 per cent of weed seeds and other foreign materials, and no portion of the stated 4 per cent of weed seeds and other foreign materials shall be intentionally added. (Adopted prior to 1928.)

61. **Unscreened Flaxseed Oil Feed Cake** is the product obtained by extraction of part of the oil from unscreened flaxseed by crushing, cooking and hydraulic pressure, or by crushing, heating and the use of solvents. The ingredients must be stated as "partially extracted flaxseed and foreign seeds (wheat, wild buckwheat, pigeon grass, wild mustard, etc.)." (Adopted prior to 1928.)

62. **Ground Unscreened Flaxseed Oil Feed** is the ground unscreened flaxseed oil feed cake. (Adopted prior to 1928.)

63. **Screenings Oil Feed** is the ground product obtained after extraction of part of the oil by crushing, cooking and hydraulic pressure, or by crushing, heating and the use of solvents from the smaller imperfect flaxseed, weed seeds and other foreign materials having feeding value, separated in cleaning flaxseed. The name of the grain from which the screenings are separated must be prefixed to "screenings oil feed." (Adopted prior to 1928.)

64.....**Per Cent Protein Oil Cake** is the product obtained after the extraction of part of the oil by crushing, cooking, and hydraulic pressure, or by crushing, heating and the use of solvents, from flaxseed which have been screened and cleaned of weed seeds and other foreign materials by the most improved commercial process. When used alone the term "Oil Cake" shall be understood to designate linseed cake as defined. When used to cover any other product the name of the seed from which it is obtained must be prefixed to the words "Oil Cake." (Adopted prior to 1928.)

65.....**Per Cent Protein Oil Meal or....Per Cent Protein Ground Oil Cake** is oil cake ground to a meal. (Adopted prior to 1928.)

Marine Products

66. **Fish Meal** (Feeding) is clean, dried, ground tissues of undecomposed whole fish and/or fish cuttings with or without the extraction of part of the oil, and contains not more than 3 per cent of salt (NaCl). If it contains more than 3 per cent of salt (NaCl) the amount of salt must constitute a part of the brand name, provided that in no case shall the salt content of this product exceed 7 per cent. (Adopted 1933.)

67. **Fish Residue Meal** (Feeding) is the clean, dried, undecomposed residue from the manufacture of glue from non-oily fish, and contains not more than 3 per cent of salt (NaCl). If it contains more than 3 per cent of salt (NaCl) the amount of salt must constitute a part of the brand name, provided that in no case shall the salt content of this product exceed 7 per cent. (Adopted 1933.)

68. **Crab Meal** (Feeding) is prepared from the undecomposed dried waste of the crab industry and contains the shell, viscera and part or all of the flesh. It contains not less than 25 per cent of protein and not more than 3 per cent of salt (NaCl). If it contains more than 3 per cent of salt (NaCl) the amount

of salt must constitute a part of the brand name, provided that in no case shall the salt content of this product exceed 7 per cent. (Adopted 1933.)

69. **Shrimp Meal** (Feeding) is prepared from the undecomposed dried waste of the shrimp industry and contains the heads, hull and/or the whole shrimp and not more than 3 per cent of salt (NaCl). If it contains more than 3 per cent of salt (NaCl) the amount of salt must constitute a part of the brand name, provided that in no case shall the salt content of this product exceed 7 per cent. (Adopted 1933.)

70. **Whale Meal** (Feeding) is prepared from the clean, dried undecomposed flesh of the whale, after part of the oil has been extracted. It contains not more than 3 per cent of salt (NaCl). If it contains more than 3 per cent of salt (NaCl) the amount of salt must constitute a part of the brand name, provided that in no case shall the salt content of this product exceed 7 per cent. (Adopted 1933.)

71. **Cod Liver Oil** is the product obtained by extraction of part of the oil from cod livers. (Adopted 1932.)

72. **Sardine Oil or Pilchard Oil** is the product obtained by extraction of part of the oil from the whole Pacific sardine or pilchard or from cannery refuse of this species of fish. (Adopted 1932.)

73. **Salmon Oil** is the product obtained by extraction of part of the oil from the cannery refuse of salmon. (Adopted 1932.)

74. **Tuna Oil** is the product obtained by extraction of part of the oil from the cannery refuse of tuna. (Adopted 1932.)

75. **Menhaden Oil** is the product obtained by extraction of part of the oil from whole menhaden. (Adopted 1932.)

76. **Herring Oil** is the product obtained by extraction of part of the oil from the whole herring or part of the herring. (Adopted 1933.)

77. **Salmon Liver Oil** is the product obtained by extraction of part of the oil from salmon livers. (Adopted 1933.)

78. **Stearine (Feeding)** is the solid material obtained by filtration from an animal or vegetable oil after chilling or freezing in the process of refining. When this product is sold as a feed, the term shall be prefixed by the name of the oil from which it is obtained. (Adopted 1934.)

Milk Products

79. **Dried Buttermilk** (Feeding) is the product resulting from the removal of water from clean, sound buttermilk derived from natural cream to which no foreign substances have been added, excepting such as are necessary and permitted in the manufacture of butter. It contains not more than 8 per cent of moisture, not more than 13 per cent of mineral matter (ash), and not less than 5 per cent of butterfat, as determined by the Roese-Gottlieb method. (Adopted 1932.)

80. **Evaporated Buttermilk** (Feeding), **Concentrated Buttermilk** (Feeding) or **Condensed Buttermilk** (Feeding) is the product resulting from the removal of a considerable portion of water from clean, sound buttermilk derived from natural cream to which no foreign substances have been added excepting such as are permitted and necessary in the manufacture of butter. It contains not less than 27 per cent of total solids, not less than 2 per cent of butterfat, and not more than .14 per cent of ash for each per cent of solids. This definition does not prohibit the use of a distinctive trade name, provided it is followed by one of the names given. (Adopted prior to 1928.)

81. **Dried Skimmed Milk** (Feeding) is the product resulting from the removal of water from clean, sound skimmed milk. It contains not more than 8 per cent of moisture. (Adopted 1930.)

82. **Dried Soured Skimmed Milk** (Feeding) is the product resulting from the removal of water from clean, sound skimmed milk which has been soured by a suitable culture of lactic bacteria. It contains not more than 8 per cent moisture. (Adopted 1932.)

83. **Evaporated Soured Skimmed Milk** (Feeding), **Concentrated Soured Skimmed Milk** (Feeding) or **Condensed Soured Skimmed Milk** (Feeding) is the product resulting from the removal of a considerable portion of water from clean, sound skimmed milk which has been soured by a suitable culture of lactic bacteria. It contains not less than 27 per cent of total solids. (Adopted 1932.)

84. **Condensed Skimmed Milk** (Feeding) is the product resulting from the removal of a considerable portion of water from clean, sound skimmed milk. It contains not less than 27 per cent of total solids. (Adopted 1930.)

85. **Milk Sugar Feed or Dried Whey** (Feeding) is the by-product from the manufacture of cheese and should contain at least 70 per cent of lactose (milk sugar). (Adopted 1932.)

86. **Dried Whey** (Feeding) is the by-product from the manufacture of cheese and/or casein. This product shall contain at least 65 per cent of lactose (milk sugar.) (Adopted 1934.)

Mineral Feeds

87. Mixed feeds containing both feed and more than 5 per cent of mineral ingredients requires, in addition to the usual declaration of the chemical feed analysis, a declaration of each ingredient contained therein and the minimum percentages of lime expressed as CaO, phosphoric acid expressed as P_2O_5, iodine (I), and the maximum percentage of salt (NaCl) if same be present. If minerals predominate in the mixture, the usual declaration of the chemical feed analysis, with the exception of protein, may be omitted.

In mineral feeds containing no organic ingredient, the usual chemical feed guarantee need not be made. A declaration should be made of each ingredient contained therein and the minimum percentage of lime expressed as CaO, phosphoric acid expressed as P_2O_5, iodine (I), and the maximum percentage of salt (NaCl) if same be present.

The mineral ingredients should be stated in the common English terms, if any such terms exist.

It being impossible to classify separately the drug ingredients and the mineral ingredients, be it resolved:

(a) That all mixtures containing mineral ingredients generally regarded as dietary factors essential for the normal nutrition of animals and which are sold or represented for the primary purpose of supplying these minerals as additions to rations in which these same mineral factors may be deficient, be classified as mineral feeds.

(b) That all other preparations which are sold or represented primarily for the cure, mitigation or prevention of disease be classified by this Association as drugs, medicines or specifics. (Adopted prior to 1928.)

Oat Products

88. **Oat Hulls** is the product consisting of the outer covering of the oat. (Adopted prior to 1928.)

89. **Oat Middlings** is the product consisting of the floury portions of the oat groat obtained in the milling of rolled oats. (Adopted prior to 1928.)

90. **Oat Shorts** is the product consisting of the covering of the oat grain lying immediately inside the hull, being a fuzzy material carrying with it considerable portions of the fine floury part of the groat obtained in the milling of rolled oats. (Adopted prior to 1928.)

91. **Oat Chop, Ground Oats, Pulverized Oats, Crushed Oats, or Crimped Oats** consists of the entire product made by chopping, cutting, grinding, crushing, or crimping whole oats. (Adopted 1931.)

92. **Oat Groats** are the kernels produced from cleaned and dried oats in the process of manufacturing oat meal. (Adopted 1931.)

93. **Hulled Oats, or Undried Oat Groats** are the kernels produced from the undried grain in the process of hulling oats. (Adopted 1931.)

94. **Oat Meal, or Ground Oat Groats** is the product produced by cutting, cracking or grinding oat groats. (Adopted 1931.)

95. **Rolled Oat Groats or Rolled Oats** is the product obtained in the process of rolling oat groats. (Adopted 1931.)

96. **Clipped Oat By-Products** is the by-product obtained in the manufacture of clipped oats. It may contain the light chaffy material broken from the end of the hulls, empty hulls, light immature oats and dust. It must not contain an excessive amount of oat hulls. (Adopted prior to 1928.)

97. **Oat Mill Feed** (Oat Hulls, Oat Shorts and Oat Middlings) is the entire by-product produced in the manufacture of Oat groats and consists of oat hulls, oat shorts and oat middlings. If used in a mixed feed, it shall be called Oat Mill Feed (Oat Hulls, Oat Shorts and Oat Middlings). (Adopted 1932.)

Palm Products

98. **Palm Kernel Oil Meal** is the ground residue from the extraction of part of the oil by pressure or solvents from the kernel of the fruit of Elaeis guineensis or Elaeis molanococco. (Adopted prior to 1928.)

Peanut Products

99. **.....Per Cent Protein Peanut Oil Cake** is the residue after the extraction of part of the oil by pressure or solvents from peanut kernels. (Adopted prior to 1928.)

100. **.....Per Cent Protein Peanut Oil Meal** is ground peanut oil cake. (Adopted prior to 1928.)

101. **Unhulled Peanut Oil Feed** is the ground residue obtained after extraction of part of the oil from whole peanuts, and the ingredients must be designated as **Peanut Meal and Hulls.** (Adopted prior to 1928.)

Rice Products

102. **Rice Bran** is the pericarp or bran layer of the rice, with only such quantity of hull fragments as is unavoidable in the regular milling of rice. (Adopted prior to 1928.)

103. **Rice Hulls** is the product consisting of the outer coverings of the rice. (Adopted prior to 1928.)

104. **Rice Polish** is the finely powdered material obtained in polishing the kernel. (Adopted prior to 1928.)

105. **Rice Meal** is ground brown rice or ground rice after the hull has been removed. (Adopted prior to 1928.)

106. **Ground Rough Rice** is ground rice from which the hull has not been removed or ground paddy rice. (Adopted prior to 1928.)

107. **Rice Stone Bran** is the siftings from the materials secured in removing hulls from rice and contains rice germs, broken rice and some rice hulls. (Adopted prior to 1928.)

108. **Rice Huller Bran** is a product secured by the huller and comes from brown rice and consists mostly of the bran and germs. (Adopted prior to 1928.)

Rye Products

109. **Rye Bran** is the coarse outer covering of the rye kernel as separated from the cleaned and scoured rye. (Adopted prior to 1928.)

110. **Rye Feed** is a by-product obtained in the usual process of the milling of rye flour from cleaned and scoured rye grain, consisting principally of the mill-run of the outer covering of the rye grain and the germ with small quantities of flour and aleurone. (Adopted prior to 1928.)

111. **Rye Red Dog** is a by-product obtained in the usual process of the milling of rye flour, consisting principally of aleurone with small quantities of flour and fine bran particles and must not contain more than 3.5 per cent of crude fiber. (Adopted prior to 1928.)

112. **Rye Low-Grade Feed Flour** consists principally of dark rye flour and small quantities of aleurone and fine bran particles and must not contain more than 1.5 per cent of crude fiber. (Adopted prior to 1928.)

113. **Rye Middlings** consists of rye feed and rye red dog combined in the proportions obtained in the usual process of milling rye flour. (Adopted prior to 1928.)

114. **Rye Flour Middlings** consist of rye feed, rye red dog and pure dark rye flour combined in the proportions obtained in the milling of rye flour and must not contain more than 5 per cent of crude fibre. (Adopted prior to 1928.)

Screenings

115. **Screenings** consist of the smaller imperfect grains, weed seeds, and other foreign materials, having feed value, separated in cleaning the grain. (Adopted prior to 1928.)

116. **Scourings** consist of such portions of the cuticle, brush, white caps, dust, smut and other materials as are separated from the grain in the usual commercial process of scouring. (Adopted prior to 1928.)

(NOTE) If to any of the wheat or rye by-product feeds there should be added screenings or scourings—as above defined, either ground or unground, bolted or unbolted, such brand shall be so registered, labeled and sold as clearly to indicate this fact. The word "Screenings," or "Scourings," as the case may be, shall appear as part of the name or brand and shall be printed in the same size and face of type as the remainder of the brand name. When the word "Screenings" appears it is not necessary to show also on the labeling the word "Scourings." (Adopted prior to 1928.)

Sorghum Products

117. **Head Chops** is the product consisting of the entire heads of the grain sorghums chopped, and should bear the name of the sorghum from which it is made. This includes, among others, kaffir head chops, milo head chops, feterita head chops, and sorghum head chops. (Adopted prior to 1928.)

118. **Head Stems** is the product consisting of the stems from the heads of the grain sorghums after the grain has been removed, and should bear the name of the sorghum from which it is made. (Adopted prior to 1928.)

Soybean Products

119. **Ground Soybeans** is the product obtained by grinding whole soybeans without cooking or removing any of the oil. (Adopted 1933.)

120.....**Per Cent Protein Soybean Oil Cake or Soybean Oil Chips** is the product obtained by crushing, cooking and removing part of the oil from soybeans. (Adopted 1933.)

121.....**Per Cent Protein Soybean Oil Meal** is ground soybean oil cake or ground soybean oil chips. (Adopted 1933.)

LIBRARY

Velvet Bean Products

122. **Velvet Bean Meal** is ground velvet beans containing only an unavoidable trace of hulls or pods. (Adopted prior to 1928.)

123. **Ground Velvet Bean and Pod** is the product derived by grinding velvet beans with the pod. It contains no additional pods or other materials. (Adopted prior to 1928.)

Wheat Products

124. **Wheat Bran** is the coarse outer covering of the wheat kernel as separated from cleaned and scoured wheat in the usual process of commercial milling. (Adopted prior to 1928.)

125. **Wheat Standard Middlings** consists mostly of fine particles of wheat bran, wheat germ, and very little of the fibrous offal obtained from the "tail of the mill." This product must be obtained in the usual commercial process of milling and must not contain more than 9.5 per cent of crude fiber. (Adopted prior to 1928.)

126. **Wheat Flour Middlings** shall consist of wheat standard middlings and wheat red dog combined in the proportions obtained in the usual process of milling and must not contain more than 6.0 per cent of crude fiber. (Adopted prior to 1928.)

127. **Wheat Red Dog** is a by-product obtained in the usual commercial process of flour milling, consisting principally of aleurone with small quantities of wheat flour and fine wheat bran particles and must not contain more than 4.0 per cent of crude fiber. (Adopted prior to 1928.)

128. **Wheat Low-Grade Feed Flour** is a by-product obtained in the usual commercial process of flour milling, consisting principally of wheat flour with small quantities of aleurone and fine wheat bran particles and must not contain more than 1.5 per cent of crude fiber. (Adopted prior to 1928.)

129. **Wheat Bran and Wheat Standard Middlings** consists of the two commodities as defined above, mixed in the proportions obtained in the usual process of commercial milling. (Adopted prior to 1928.)

130. **Hard Wheat Mixed Feed** (mill-run wheat feed) consists of wheat bran and wheat flour middlings combined in the proportions obtained in the usual process of commercial milling. This product must not contain more than 9.5 per cent of crude fiber. (Adopted prior to 1928.)

131. **Wheat Brown Shorts** (Wheat Red Shorts) consists mostly of the fine particles of wheat bran, wheat germ and very little of the fibrous offal obtained from the "tail of the mill." This product must be obtained in the usual commercial process of milling and must not contain more than 7.5 per cent of crude fiber. (Adopted prior to 1928.)

132. **Wheat Gray Shorts** (Wheat Gray Middlings or Wheat Total Shorts) consists of the fine particles of the outer bran, the inner bran or bee-wing bran, the germ and the offal or fibrous materials obtained from the "tail of the mill." This product must be obtained in the usual process of commercial milling and must not contain more than 6.0 per cent of crude fiber. (Adopted prior to 1928.)

133. **Wheat White Shorts or Wheat White Middlings** consists of a small portion of the fine wheat bran particles and the wheat germ and a large portion of the fibrous offal obtained from the "tail of the mill." This product must be obtained in the usual process of flour milling and must not contain more than 3.5 per cent of crude fiber. (Adopted prior to 1928.)

134. **Wheat Mixed Feed** (Mill-run wheat feed) consists of wheat bran and the gray or total shorts combined in the proportions obtained in the usual process of commercial milling. This product must not contain more than 8.5 per cent of crude fiber. (Adopted prior to 1928.)

INSECT PESTS OF MINT

George E. Gould

Department of Entomology

The mint crop has been considered as unusually free from attacks by insects, with no major pests until the advent of the mint fleabeetle. In 1926 this fleabeetle was discovered to be rather widespread in the muck areas of St. Joseph County, where it caused considerable damage to both peppermint and spearmint. Since then it has spread through the principal mint sections of the state and is a serious menace to profitable mint production. In addition to the fleabeetle several other insects are found attacking the crop every year, in greater or lesser numbers. The early recognition of these pests and their injury is important to the grower in order that he may apply proper remedial measures to protect his crop.

The muck regions of Northern Indiana and Southern Michigan are well adapted climatically to the production of mint. About half of the world's output of peppermint and spearmint oils is produced in this region.* In Indiana many growers follow the practice of leaving the mint on the soil for six to ten years before changing to another crop. With the spread and increase of the mint fleabeetle a short rotation is becoming a necessity.

The Mint Fleabeetle

The first authentic record of the mint fleabeetle (*Longitarsus waterhousei* Kutsch.) in Indiana was made by L. G. Gentner near Mishawaka on October 21, 1925. Growers in some localities visited by Gentner reported injury as early as 1922. Beetles were collected in Michigan in 1922 and were reported by growers as having been present for six to eight years previous. This fleabeetle has been known as an enemy of mint in Europe for some time and it is frequently a serious problem. The insects apparently came into this country through the shipment of mint roots from England to Canada, some of which were brought in as early as 1870.

In Indiana the mint fleabeetle and its injury has been observed in eight counties: Elkhart, Fulton, Kosciusko, LaPorte, Marshall, St. Joseph, Starke and Whitley. No doubt it is present in the mint fields of the adjoining counties, although growers have not called it to our attention yet. The spread appears to be toward the east and within a year or two all mint sections will probably be infested. Field collections in 1933 showed a small population in fields in Whitley County, while in Kosciusko and other counties to the west severe damage was recorded. The southern limit of the infestation is not known but beetles have been collected about two miles south of Akron in Fulton County. Commercial mint fields are seldom found south of this.

Life history. In the life cycle of this insect occurs the four stages, egg, larva, pupa and adult, typical of all beetles. The egg is quite small, being 1/40 of an inch long, and is orange-yellow in color. The larva is 1/5 of an inch long and whitish in color, while the pupa is only half as long. The adult beetle is approximately 1/12 of an inch in length. Its color is pale brown and the hind legs are enlarged for jumping. The female is slightly larger than the male and has the second or membraneous wings developed for flying.

---

* C. B. Sayre. Mint Growing in Northern Indiana. Purdue University Agricultural Experiment Station Circular No. 65, 1917.

Eggs are laid in the loose muck from August until the death of the females in the fall. No special care in oviposition has been observed, for the female deposits the eggs singly in the upper inch or so of soil about the mint roots. In the fall when the mint sod is plowed under for winter protection, the eggs are also covered over by four or five inches of soil and plants. In this situation the eggs remain until they hatch about the middle of May. The small larvae crawl to the nearby roots to feed, all underground portions of the plants being attacked. They destroy the small roots by feeding externally, while the larger roots are girdled and tunnelled. Larvae reach maturity in four or five weeks and pupate in the soil. Eight to 20 days are required in this stage before the beetles emerge and crawl to the surface where they commence to feed on the mint foliage. The length of time in each stage varies with the food supply and climatic conditions.

Beetle emergence starts from the first to the tenth of July, varying with the season and the locality, while the peak of adult abundance is reached late in the month. Beetles feed for two or three weeks before oviposition, so that the first eggs are laid about August 1. These facts have an important bearing on control, as the most efficient results are obtained through the use of insecticides applied as near the peak of abundance as possible and yet before oviposition takes place. There is a single generation a year with a seven to nine months' period in the egg stage.

Feeding habits. The food plants of the fleabeetle, so far as known, are all members of the mint family, with the adults feeding on the foliage and the larvae on the roots. Peppermint (*Mentha piperita* L.) is the preferred host, although spearmint (*M. spicata* L.) is severely attacked. Beetles were collected also on a species of Mentha growing wild along a small stream of water. A. W. Trippel collected numerous specimens on *Calamintha alpina*, a cultivated mint in his garden at Mishawaka. Other members of the mint and related families, including catnip (*Nepeta cataria* L.), are found in and around cultivated fields, but were never attacked, even though the peppermint was severely injured.

The beetles prefer to feed upon the terminal growth where they eat small, circular holes in the leaves and occasionally bite into the stems. During the heat of the day a tendency is shown to stay in the shade and most beetles are found on the lower stems or on the ground beneath the plants. The extremely high temperatures on the soil surface in the sun is usually fatal to any unwary individual alighting there. Since the oil accumulates in the leaves, any condition affecting the foliage influences the yield of oil. Severely damaged plants are characterized by their brown, almost leafless appearance.

Larval damage to the root system of the plants is of a more serious nature for, if these parts are destroyed, the plant has little chance for recovery. Small rootlets are fed on first and then the larger roots are attacked. Sometimes they are girdled, while others are tunnelled for a distance of several inches by the larvae. At times the larvae even work up in the stems an inch or so above ground. The destruction of the roots soon shows in the appearance of the plant. It is stunted in growth and takes on the reddish color of frost-injured plants. The number of new shoots put out is greatly reduced and such a plant does well to survive the attack. Of course, the damage to any one plant depends largely upon the number of insects present and the vigor of the plant itself.

Spread. The mint fleabeetle is spread by three methods: hopping, flight of the females and the carrying of larvae or eggs on the mint roots in setting out new fields. Little migration takes place as long as plenty of food is present. However, when the mint is cut, the beetles hop in all directions. On the loads of mint hay going to the still, the insects are abundant and, of course, are spread along the road. The unloading platform at the still is alive with beetles. Those fields adjoining the still always have the heaviest infestations on the farm, which suggests that the location of the still should be as far distant as possible from the mint fields.

The female beetle has the hind wings developed and is capable of flight, although this is seldom observed. Beetles collected on ornamental mint in Mishawaka were more than three miles from mint fields. Distances that they can hop or fly has never been determined but, when one sees how abundant wild and volunteer mint is in Northern Indiana, the rapid spread of this pest is easily understood.

In the past the method of planting a new field was to plow up the mint roots early in the spring and after removing much of the soil, to set them out in rows in the new location. Recently many growers are transplanting small plants about six inches high during May and June and, occasionally, July. This practice requires more soil to remain on the roots to give the plant a start. Since either the eggs, larvae or pupae are in the soil at this time, it is easy to understand how these stages are established in a new field. In 1934 an unusual condition existed in the mint area, for about three-fourths of the fields were killed by a late frost and resetting in some instances continued until late July. Where mint was set in the old mint fields, there was an abundance of insects in the soil which immediately concentrated their activities on the newly placed plants. Consequently, growers had poorer stands in August than they have had for several years.

Control. Experiments have been conducted in Northern Indiana for three seasons to determine the most effective method or material to control this insect and, secondly, the best time to apply such a control. Since eight to ten months in the cycle are spent in the soil, control of the foliage-feeding stage is necessary. As mentioned before the practice of plowing under the mint sod in the fall for winter protection, also plows the eggs under to a depth of four to six inches where they are little influenced by freezing weather. Frequent rotation is advisable in the beetle-infested fields, provided, of course, all volunteer mint is eliminated when other crops are being grown. The destruction of wild mint around the edge of the field and along ditch banks is also essential. Many growers follow the practice of summer fallowing a field at least one year before setting to mint. In such fields all wild or volunteer plants must be destroyed.

Observations on the life cycle show that the newly emerged beetles feed for two or three weeks before mating and egg-laying. The peak of emergence is reached about four weeks after the first beetles are found or about August 1. From these two observations, then, it is evident that the majority of the beetles are feeding on the foliage by the last ten days of July, and yet few eggs have been laid. Consequently, the treatment attempting to kill the beetles should be applied during or shortly after this period. In other words —treatment should start about July 20, and should be completed by August 5.

Insecticide tests were conducted in both laboratory and field to determine the most effective materials. The best results were obtained through the use of calcium arsenate on the growing mint and a Paris green mixture on the mint stubble. Calcium arsenate, when diluted with five to ten per cent bentonite or dusting clay as a sticker, is applied at the rate of 15 pounds to the acre, while a 50 per cent dust is applied at about 25 pounds to the acre. After the mint is harvested, a Paris green-flour mixture at 1-9 dilution is safe to use. This mixture gives a better kill but can not be used on the growing mint. Barium fluosilicate gave a higher percentage of control in cage tests, but caused some injury to plants in the field.

Both the calcium arsenate and Paris green mixtures should be applied at night or early in the morning when dew is present and very little breeze blowing. When the standing mint is dusted with calcium arsenate, it should not be used as hay for animals after the oil is distilled from it. In those seasons when the insecticide applications will interfere with the normal harvesting of the crop, it is advisable to cut the mint a week or so early. Then the Paris green mixture can be applied to the mint stubble at the proper time to obtain the most efficient results.

Special care should be taken to prevent infestation of first-year mint. When ready to cut a field of meadow mint adjoining row mint, a 20-foot border strip should be thoroughly poisoned and left uncut to kill the beetles as they migrate from the stubble. In that portion of the farm where plants for transplanting in the new field are to be obtained, special care should be taken to kill all beetles. At least three applications should be made to such areas. Then, in the transplanting procedure, as much soil as possible should be knocked from the roots. Plants set out after July 10 should be dipped in a solution of arsenate of lead (six pounds in 50 gallons of water) and allowed to dry. If no rain occurs, this poison will protect the plants during the first week or ten days after transplanting in the new field.

Cutworms

Cutworms are a group of caterpillars which have the habit of feeding on low-growing plants, cutting off the stems near the soil surface. The adult stage of these insects is a brownish or grayish moth with wing expanse of an inch and a half. In the mint fields a number of different species occur but, as they all have a similar life history and the same control measures, they are grouped here under one heading.

The moths fly at night and feed upon the nectar of various plants. The females lay their eggs preferably on grass in the fields. Eggs hatch in August and September and the young caterpillars feed upon grass and other vegetation until frost. Winter is passed as a half grown caterpillar at the roots of the plants. The following spring they emerge and feed voraciously upon various plants. Cutworms become full grown in June and July when they pupate in cells a few inches below the surface of the soil. The moths emerge in July and August and deposit eggs for the next generation. Thus, there is a single generation of most species each year.

In the mint fields cutworms are frequently serious pests in the spring and early summer, especially in areas where grass is abundant. Seasons with a cold, wet spring are especially favorable to cutworms. Plants are attacked at the surface of the muck and are cut completely off, as are also the upper roots.

The usual practice of plowing under mint sod in the fall aids in keeping down the cutworm population. Poisoned bran bait is best method to destroy the caterpillars when they become abundant in the spring. This bait is prepared by mixing together 25 pounds of bran, Paris green (white arsenic or sodium arsenite may be substituted) one pound, cheap molasses two quarts, and water two to three gallons. The poison and bran are mixed dry and the molasses is diluted with some water. Then the liquid is added to the poisoned bran, mixed and more water added, until the mixture is damp enough to stick together. It should be broadcasted late in the evening as the cutworms work at night. The usual rate is 15 to 20 pounds per acre with somewhat more in grassy and weedy fields.

Grasshoppers

Grasshoppers are another group of general feeders which occasionally attack mint. As a rule, feeding on mint takes place along the edges of the field where the grasshoppers move in from adjoining grass land. In all stages the grasshopper is a big eater and can strip the leaves from mint plants in a short time.

Females lay their eggs in sodlands, clover fields and weedy areas, as a rule from August to late fall. A clay or loam soil is preferred for this purpose and muck is avoided. Eggs hatch the following spring into small nymphs, which feed upon grass crops as long as they are present and then may migrate to neighboring fields. Nymphs grow in size during the summer and by August are mature with fully developed wings. Damage to mint seldom occurs beyond a hundred feet from the edge of the field.

Cultural practices such as fall plowing and the destruction of feeding places along the edge of mint fields will greatly reduce the grasshopper population. The scattering of poisoned bran bait mentioned under cutworm control is quite effective in controlling grasshoppers. The bait should be put out in the early morning as the insects are feeding at that time. Both the grassy areas and the edge of the mint field should be covered with the bait.

Wireworms

Wireworms are frequently found in muck soils with poor drainage or a high water level. These insects are an inch long, hard and light brown in color. Their favorite food is members of the grass family, but mint is attacked when these are not present. The adult stage of the wireworm is a beetle known as a "skip-jack" or click-beetle.

Drainage of the land aids in reducing the number of wireworms in the soil. Mint should not follow a grass crop and should not be planted the first season sod land is broken up. In the rotation practice one or two crops of clover, alfalfa or buckwheat should precede mint.

White Grubs

In certain sections of the state white grubs are a serious problem on muck soils. The adult of the grub, which is commonly known as a June beetle, prefers to lay eggs in sod land. Since the grub stage lives in the soil for nearly three years, the suggestions for the control of wireworms would also apply to white grubs.

Millipeds

Millipeds belong to a group of animals closely allied to insects. They are characterized by their round, wire-like form and have two pairs of legs to each body segment. Occurring in soils with a high humus content, they are frequently abundant in muck land. Their food apparently is decaying vegetable matter but they do attack a number of growing plants. In recent years millipeds have been recorded as damaging potatoes, carrots, corn and mint in Northern Indiana. An interesting example of injury to all kinds of plants in a home garden was reported from Nappanee in 1932. A load of mint hay, which had been decaying on a mint field for two years, was hauled in and spread on the garden as fertilizer. In the following years the millipeds increased to such an extent that all plants were killed in 1932.

Control of millipeds in a muck soil is difficult, as the pests feed on the roots and are never exposed to the surface. Acid soils are somewhat repellent to them but certain species even prefer that type of soil. During 1932 a muck field near Nappanee was under observation, in which millipeds were exceptionally numerous and were damaging potatoes and mint. Following a heavy rain in July, water backed up in the drainage ditches and overflowed most of the potato land. Four days later when the water receded, dead millipeds were found in great numbers in the soil depressions. Since then the grower has had no trouble on that portion of the farm.

As millipeds prefer soils with much decaying vegetable matter present, an effort should be made to remedy this condition, if at all possible. Old mint hay should not be scattered about on infested fields. The practice of plowing under a green crop as fertilizer should likewise be avoided. Summer fallowing of the soil for a year or two before setting to mint is of value not only for milliped control but for other insects as well.

Crane Fly Maggots

Mint is occasionally injured by crane fly maggots of several species. *Tipula mingwe* Alex. is recorded by Pettit as causing severe damage in Michigan in 1929 (5). The maggots are called "leather-jackets" and eat notches in the roots and stems at or below the surface of the ground. The maggots are an inch long, gray, leathery in texture and have four protuberances on the head. In the adult stage this insect is a long-legged, two-winged fly.

As a rule the maggots live at or near the soil surface where they feed on decaying vegetable matter and sometimes on the roots of grasses. They prefer moist conditions where there is a rank growth of grass. Injury to mint is found in small areas and to date has not warranted the development of controls.

Plant Lice

Several species of plant lice occur on field mint but no serious infestation has been observed to date. Plants used in the laboratory for insecticide tests were severely infested with *Phorodon menthae* (Buckton) (Mason det.). A decided preference was shown for the terminal growth with most of the lice feeding on the stems, although a few were found on the undersides of the leaves. In a few weeks' time the stems became twisted and the leaves curled so that the plants had to be discarded. The field infestations observed to date would not warrant the usual insecticide control operations recommended for plant lice.

Thrips

Thrips are commonly found on various mint plants, although the infestation is usually light and little damage results. The species observed in Indiana was thought to be *Thrips tabaci* Linde. Gentner (3) in Michigan reports that several acres of spearmint were infested with *Thrips nigropilosus* Uzel in 1928. The infestation coming a short time before harvest reduced the oil content of the plants by causing most of the leaves to drop. Dusting with sulphur followed by two heavy rains eliminated further trouble. Morgan in 1925 describes a new species of thrips, *Frankliniella gilmorei* from Tennessee (4) on mint. As in the case of plant lice, the infestations by thrips that have been observed would not warrant insecticide treatment.

Mint Looper

During August and September of 1934 both peppermint and spearmint plants in experimental plots of the Department of Botany at Lafayette were severely injured by a looper, *Autographa ou* Gn. (Benjamin det.). The terminal growth was attacked with the leaves and some of the stems being eaten. The plots had a very ragged appearance from the attack of this caterpillar. About 20 loopers were collected and placed in cages for rearing but all were killed by parasites. Of a second lot of ten specimens, three pupated and the moths emerged in October. The looper resembles the cabbage looper somewhat, but is slightly longer, more hairy and of a darker green color.

In preparing for pupation the caterpillar webs together the leaves of several terminal shoots. This case is about an inch in length and a half inch across. Instead of the usual round pupal case the sides and ends are angular. The case is inconspicuous because of the leaves and stems woven in the silk. Two species of parasites were found. The common species was a small hymenopteran which kills the larvae before the final molt into the pupae. The larval skin is packed tight with small pupal cells of the parasites (determined as *Copidosoma trumcatellum* Dalm. by Gahan). Although no definite count was made of the number present, there must have been several hundred. The other parasites were flies of the family Tachinidae, which killed the insect immediately after pupation. In the pupal case from one to three dipterous pupae were found. Both parasites emerged in October. A predaceous stink bug, *Perillus bioculatus* Fabr., was captured while feeding upon a looper.

The looper can be controlled by the use of the common arsenical poisons.

Miscellaneous Insects on Mint

A number of insects feed upon mint, but rarely become a serious problem. The corn earworm (*Heliothis obsoleta* Fabr.) was reported from Laporte County as damaging mint in October 1934. This pest was unusually abundant during the season and fed upon a number of different plants. A small, brightly spotted moth, *Sparganothis sulfureana* Clemens (Busck det.) was reared from peppermint in the Botany plots. The larva had spun up in a small silken case on a terminal shoot.

In making studies of the insect populations of mint fields, a number of different insects are collected. These fall into three groups: those feeding on mint, those preying upon the mint insects, and those alighting there by chance. It is difficult to separate the insects into the various groups without definite records of feeding. Among the Hemiptera at least two species, the tarnished plant bug (*Lygus pratensis oblineatus* Say), and the rapid plant bug (*Adelphocoris rapidus* Say), do some feeding on the plants.

In the family of leaf-feeding beetles, Chrysomelidae, 13 species were collected on mint. Of these, three species were definitely known to have been feeding when captured. These are *Longitarsus waterhousei* Kutsch. (already discussed as the mint fleabeetle), *Lema trilineata* Oliv. and *Chaetocnema denticulata* Ill. Among the other species the following were collected on cultivated mint: *Systena taenida blanda* Melsh., *Systena frontalis Fab.*, *Longitarsus suspectus* Blatch., *Phyllotreta zimmermanni* Cr., *Psylliodes punctata* Melsh., *Epitrix fuscula* Cr., and *E. cucumeris* Harris. In addition to the last two mentioned, the following two species were collected on wild mint: *Pachybrachys atomarius* Melsh. and *P. othonus* Say.

This circular is a report of the inspection of commercial fertilizers for the year 1934. The inspectors visited every county in the state in both the spring and fall seasons and collected 1,425 official samples.

The Indiana Fertilizer Law is essentially a correct labeling act. It protects the honest and efficient manufacturer, dealer and agent as well as the consumer. In order to obtain maximum protection, the consumer must read carefully and understand thoroughly the information on the state tag or label.

Refunds amounting to $268.23 were paid by 21 manufacturers on 58 shipments of fertilizer that were deficient in analysis.

Table 1 shows the average composition of the common fertilizer materials as well as their comparative values per ton.

Table 3 gives the tonnages of the different analyses which were in the greatest demand. The tonnage of 2-12-6 amounted to 35 per cent of all the fertilizer sold. More than 85 per cent of the total tonnage was confined to 33 analyses, while less than 15 per cent was divided among the 108 other grades as reported by manufacturers.

Table 5 shows the tonnage retail value and pounds per ton of plant food. The cost per pound of plant food was slightly higher than for any year during the previous four years. The average content of plant food (N, P_2O_5 and K_2O) sold in 1934 was 467 pounds per ton. The average analysis was 2.1 per cent nitrogen, 13.1 per cent available phosphoric acid and 6.6 per cent water soluble potash.

Table 6 gives the classified tonnage sales of low and high analysis fertilizers for the last 20 years. Table 12 shows the standing of manufacturers as determined by inspection of the year 1934. Table 13 shows the analysis of each of the 1,425 official samples collected.

COMMERCIAL FERTILIZERS

H. R. KRAYBILL, *State Chemist*
O. W. FORD, *Assistant Chemist* O. S. ROBERTS, *Chief Inspector*
Assistant Chemists, L. E. HORAT, M. H. THORNTON
Inspectors, C. M. COHEE, J. W. JACKMAN

The Indiana Fertilizer Law is essentially a correct labeling act. The intent of the law is not to determine what type of fertilizer may be sold. The law is designed to furnish the purchaser with a true statement of certain information on the state tag that will enable him to decide whether or not the fertilizer is the type that will meet his needs. The state tag gives a statement of the percentages of total nitrogen, total or available phosphoric acid, and water soluble potash. With this information the purchaser should be able to judge whether the fertilizer offered for sale meets his requirements. *In order to do this the consumer must read carefully and understand thoroughly the information on the state tag.*

The Indiana Fertilizer Law protects the honest and efficient manufacturer, dealer and agent, as well as the consumer. Full cooperation on the part of the manufacturer, dealer, agent and consumer is necessary in order to accomplish the purpose of the law.

A copy of the full text of the law will be sent to persons making request for the same to the State Chemist, Purdue University Agricultural Experiment Station, Lafayette, Indiana.

This circular presents the results of the inspection of commercial fertilizers sold in Indiana during the year 1934. It is estimated from tag sales that 152,824 tons of fertilizer were sold. From the manufacturers' reports a tonnage of 140,526 is indicated. It is believed that the latter figure represents more nearly the actual tonnage sold. The difference between the two estimates is apparently due to the fact that the manufacturers increased their stocks of tags on hand during the year. The estimated tonnage in 1934 is about 33 per cent larger than in 1933.

Inspectors from the department visited every county in the state in both the spring and fall season and collected 1,425 official samples of fertilizer. One sample was drawn for each 107 tons of fertilizer that was sold. Of these samples 1,311 were equal to or above the guarantee in value; 109 were within 10 per cent of the guaranteed value and 5 were 10 per cent or more below the guaranteed value. Eight of the 1,034 samples which contained nitrogen showed the presence of inferior nitrogen, of which three were dried manure and five were muck. Both of these materials are inferior sources of nitrogen.

REFUNDS

Every year a few cases of deficiencies occur, due to errors in labeling the fertilizer. This results from carelessness on the part of the person responsible for attaching the tags. Manufacturers should guard against such errors.

When deficiencies in analysis amounting to $1.00 or more per ton on raw materials, as calculated from the wholesale price, are found, refunds are calculated and indicated on the report of the analysis which is sent to the manufacturer and to the consumer. Refunds on mixed fertilizers are usually calculated when one ingredient is deficient to the extent of $1.00 or more per ton, regardless of the excess in amounts of the other ingredients. Nitrogen, phosphoric acid and potash play definite roles in crop production. An excess of one ingredient will not necessarily compensate for a deficiency of another.

All refunds are required to be distributed to the consumer wherever possible, and receipts for the same must be filed with the State Chemist. In case there are no records as to the consumer, the refunds may be turned over to a local charitable organization, but receipts for the same must be filed with the State Chemist.

The payment of a refund by the manufacturer to the consumer does not remove the violation, but it does indicate good intentions on the part of the manufacturer and shows his willingness to do what he can to correct the violation. However, the payment of the refund does not nullify the right of anyone in the state to call a deficiency of analysis to the attention of the prosecuting attorney.

Refunds amounting to $268.23 were paid by 21 manufacturers on 58 shipments of deficient fertilizer in 1934.

MANUFACTURERS

The term "Commercial Fertilizer" is defined by law to include all materials used for manurial purposes except barnyard manure, marl, lime, wood ashes and plaster. Barnyard manure, sheep manure and muck when dried or processed in any way come under the provisions of the law. Before any commercial fertilizer is exposed or offered for sale or sold in the state it is necessary to register the fertilizer with the State Chemist and tag it properly with Indiana State Tags or Labels. Bulk shipments must be accompanied with sufficient labels to cover the total weight of the material.

Manufacturers should not ship fertilizer without having it properly tagged with Indiana State Tags. Experience has shown that when this is done it is difficult to avoid the sale of untagged fertilizer. The State Chemist has no authority to grant permission to a manufacturer to ship unlabeled fertilizer.

AGENTS, DEALERS AND DISTRIBUTORS

Agents should familiarize themselves with the provisions of the Indiana Fertilizer Law. Each package of fertilizer offered or exposed for sale or sold in Indiana must have attached to it the Indiana State Tag bearing the facsimile signature of the State Chemist (see reproduction, page 9). *In case you receive a car of untagged fertilizer, wire the manufacturer for tags and notify the State Chemist. Do not accept the shipment until proper tags are furnished.*

Since local agents are responsible for the fertilizer that they offer for sale they should deal only with those manufacturers who agree to assume full responsibility in cases where the fertilizer fails to meet the requirements of the law.

When inspection reports show that fertilizer in your possession is deficient enough so that a refund is calculated on it, withdraw it from sale at once and notify the State Chemist, giving the date and the amount withdrawn from sale.

CONSUMERS

The Indiana State Tag is your guarantee of the fertilizer that you purchase. Read the tag. Let the analysis on the state tag be your guide rather than the brand name. Refuse to accept any fertilizer which does not have the Indiana State Tag attached to each package.

When analysis of a fertilizer is desired, do not forward a sample, but notify the State Chemist, telling how much you have on hand and send in a copy of the official label which is attached to the fertilizer.

Purchase the type of fertilizer that will meet the plant food requirements of your crops. Consult Circular No. 162 of the Purdue University Agricultural Experiment Station, entitled "Fertilizers for Indiana Soils and Crops."

CAUTION

The consumer should remember that the presence of the Indiana state label with the facsimile signature of the State Chemist does not mean that the State Chemist recommends the fertilizer. Poor quality fertilizer may be sold legally, provided it is correctly labeled. The consumer should be guided by the analysis of the fertilizer.

MEANING OF ANALYSIS

Nitrogen.—In 1881 when the Indiana Fertilizer Law was passed the principal source of nitrogen was from organic materials. The nitrogen was derived largely from such products as dried blood, bone, tankage and slaughter house by-products, garbage tankage, cotton seed meal, castor pomace, tobacco stems, manure sweepings and dried peat. Although there is little water soluble nitrogen in the above products, all carry a good source of nitrogen with the exception of garbage tankage, manure sweepings, spent tobacco stems and dried peat. In more recent years most of the animal products have been diverted into the mixed feed channels, and water soluble forms of nitrogen have taken their place in fertilizer mixtures. Today we find that most of the nitrogen carrying fertilizers have more than 80 per cent of their nitrogen content in some water soluble form.

A few of the sources of water soluble forms of nitrogen are as follows: nitrate of soda (natural and synthetic), ammonium sulphate, cal-urea, cal-nitro, urea, cyanamid and calcium nitrate.

Since water soluble forms of nitrogen are considered as readily available for plant growth, we class a fertilizer as satisfactory that has 60 per cent of its guaranteed nitrogen in water soluble form.

If less than 60 per cent of its guaranteed nitrogen is water soluble, then the availability of the insoluble organic nitrogen is determined by the alkaline permanganate method. In this case, if the active water insoluble nitrogen is equal to or greater than the inactive, the nitrogen is classed as satisfactory. If less than half of the insoluble nitrogen is active, the nitrogen is classed as inferior.

Manures and garbage tankages that have not been acidulated show an inferior quality of nitrogen. This is not the fault of the manufacturer when they are sold as manure and garbage tankage.

Phosphoric Acid.—The phosphorus in the fertilizer is linked up as chemical compounds with calcium, iron and aluminum. It may be present as mono-, di- or tricalcium phosphate.

As monocalcium phosphate $CaH_4(PO_4)_2$ it is water soluble and readily available to plants for growth.

As dicalcium phosphate $Ca_2H_2(PO_4)_2$ it is soluble in the soil solution and rendered available to plants for growth.

As tricalcium phosphate $Ca_3(PO_4)_2$ it is somewhat less available to plants.

As a complex tricalcium phosphate combined with fluorine and lime (raw rock phosphate) it is much less available to plants and becomes available only slowly in the soil.

The bulk of the fertilizer sold today contains mixtures of large amounts of mono- and dicalcium phosphate and some tricalcium phosphate. This is in contrast to the earlier years when most of the fertilizer used was bone where the phosphorus is present as tricalcium phosphate.

In acidulated goods the phosphorus is sold only on the basis of the available phosphoric acid (P_2O_5) content. The available is the sum of the soluble and reverted phosphoric acid (P_2O_5).

In bone and rock phosphate, when sold as such, the phosphorus is sold only on the basis of the total phosphoric acid (P_2O_5) content. It is only fair to state, however, that about 60 to 75 per cent of the total phosphoric acid (P_2O_5) content of bone is available by the neutral ammonium citrate method, while only from three to six per cent of the total phosphoric acid (P_2O_5) of rock phosphate is available by the same method.

Potash.—Potash, as the official label states, must be soluble in water, in which form it is considered directly available for plant use.

No difference in crop growth has been noted in American, French or German potash. Muriate of potash (KCl) being the cheapest has largely supplanted other potash salts for general crops.

AVERAGE COMPOSITION OF FERTILIZER MATERIALS

Table 1 gives the average composition of some of the more common fertilizer materials and their comparative values per ton.

TABLE 1. Average Composition and Comparative Evaluation of the Common Fertilizing Materials

Material	Nitrogen Per Cents							Phosphoric Acid Per Cents			Water Soluble Potash Per Cent	*Comparative Value Per Ton
	Total	Water Soluble Organic	Water Soluble Ammonia	Water Soluble Nitrate	Water Insoluble Organic	Active Insoluble Organic	Inactive Insoluble Organic	Total	Insoluble	Available

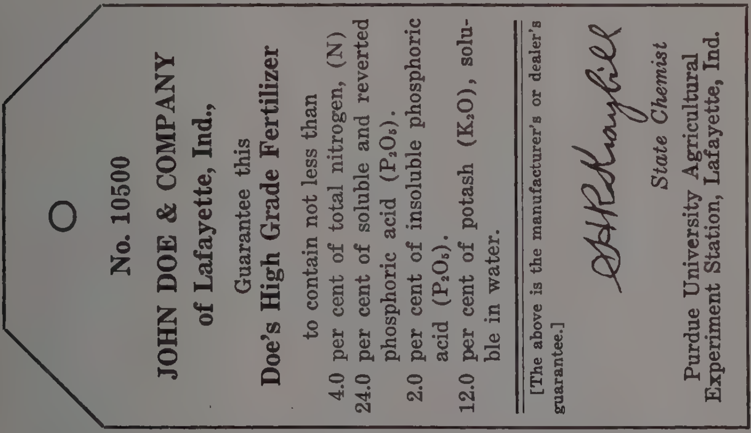
OFFICIAL STATE LABEL



No. 10500

JOHN DOE & COMPANY

of Lafayette, Ind.,

Guarantee this

Doe's High Grade Fertilizer

to contain not less than

4.0 per cent of total nitrogen, (N)

24.0 per cent of soluble and reverted phosphoric acid (P_2O_5).

2.0 per cent of insoluble phosphoric acid (P_2O_5).

12.0 per cent of potash (K_2O), soluble in water.

[The above is the manufacturer's or dealer's guarantee.]

H R Kraybill

State Chemist

Purdue University Agricultural Experiment Station, Lafayette, Ind.

The only label recognized under the law is that bearing the facsimile signature of the State Chemist. (See reproduction.) The label as issued is always printed and contains all the facts required by law; any alteration thereon constitutes a violation of the law.

Label No. 10500 guarantees that each 100 pounds of fertilizer will contain at least 4.0 pounds of total nitrogen (N), 24.0 pounds of soluble and reverted phosphoric acid (P_2O_5), and 2.0 pounds of insoluble phosphoric acid (P_2O_5), and 12.0 pounds of water soluble potash (K_2O).

We hope that it will not again be necessary to file affidavits against agents for distributing unlabeled fertilizer. There can be no excuse for shipping unlabeled fertilizer. Agents receiving same should protect themselves by refusing to accept the car. Wire the manufacturer for official labels and write the State Chemist fully concerning the unlabeled shipment.

MANY GRADES UNNECESSARY

Table 3 shows the tonnage of fertilizer sold under the different grades of analyses. In 1934 over 85 per cent of the tonnage is represented by 33 grades, while less than 15 per cent were distributed over 108 analyses. Considerable saving could be made by the manufacturer if the number of grades were reduced materially.

D. Bone Products (Steam and Raw Bone)—2,736

E. Miscellaneous—513

Summary—

1. Total tons reported—134,546
2. Tag sales from firms not reporting—5,980
3. Total tonnage based on reports (Items 1 and 2)—140,526
4. Total tonnage from tag sales—152,824

*A Available P_2O_5; I=Insoluble P_2O_5

Table 5 gives the total tonnage, retail price, cost per ton pounds of actual plant food per ton and the cost per pound o plant food for the past 14 years. It will be noted that the averag cost per pound of plant food is slightly higher in 1934 than fo any year since 1930.

1934	1,425	1,097	1,311	109	5

PRICES USED IN SECURING COMPARATIVE VALUE OF FERTILIZERS

These values are not for the purpose of fixing the commercial value of mixed fertilizers, but are for comparative purposes only. They are for use in comparing the value of inspection samples with manufacturers' guarantees, and can be used advantageously by fertilizer purchasers in calculating the relative values of various brands offered for sale by different manufacturers.

For use in determining the comparative values of fertilizer inspected in 1935 the following prices have been adopted:

Table 9. Prices Used in Determining Comparative Values of Fertilizers

	Per pound cents	Per unit or per cent dollars
All fertilizers—		
Nitrogen (N)	10.0	2.00
Soluble and reverted phosphoric acid (P_2O_5)	5.0	1.00
Potash (K_2O) soluble in water	5.0	1.00
Mixed fertilizers containing nitrogen—		
Insoluble phosphoric acid (P_2O_5)	1.5	0.30
Precipitated bone—		
Available phosphoric acid (P_2O_5)	5.0	1.00
Insoluble phosphoric acid (P_2O_5)	1.5	0.30
Animal by-products, bone, tankage, etc.—		
Total phosphoric acid (P_2O_5)	3.5	0.70
Basic Slag—		
Total phosphoric acid (P_2O_5)	4.5	0.90
Rock Phosphate (floats) and low grade slag—		
Total phosphoric acid (P_2O_5)	1.5	0.30
Mixed fertilizer, acid phosphate, etc., containing no nitrogen—		
Insoluble phosphoric acid	0.0	0.00

TABLE 10. Fertilizer Tonnage and Estimated Retail Value, 1934

Class of Fertilizer	Spring 1934 Tons	Fall 1934 Tons	Total 1934 Tons	Estimated 1934 Retail Value
1. Acid phosphate, 14% and less	63	656	719	$ 17,256 00
2. Acid phosphate, 16%	794	4,813	5,607	115,504.20
3. Acid phosphate, 18-20%	1,656	9,469	11,125	266,110.00
4. Acid phosphate above 20%	531	219	750	37,200.00
7. Ammoniated superphosphate*	406		406	28,420 00
10. Acid phosphate and potash, 14-19 units	94	531	625	15,575.00
10a. Acid phosphate and potash above 20 units	12,531	4,750	17,281	524,651.16
11. Complete fertilizer (low)	500	1,250	1,750	41,212.50
12. Complete fertilizer (medium)	563	2,181	2,744	64,291.92
13. Complete fertilizer (high)	10,750	21,169	31,919	855,110.01
13a. Complete fertilizer above 20 units	40,432	29,656	70,088	2,386,496.40
14. Steamed bone	219	1,059	1,278	39,106 80
15. Raw bone	156	2,213	2,369	76,352.87
16. Tankage	188	31	219	3,723.00
21. Rock phosphate	281	156	437	8,740.00
22. Nitrogen salts†	2,350	50	2,400	101,736.00
‡Ammonium sulphate	950		950	
‡Nitrate of soda	1,250	50	1,300	
‡Cyanamid	150		150	
23. Potash salts†	2,050	150	2,200	99,770.00
‡Muriate of potash	2,050	150	2,200	
‡Sulphate of potash				
31. Miscellaneous (peat, dried manure, dried blood, garbage tankage, etc.)	844	63	907	24,180 62
Total	74,408	78,416	152,824	$4,705,436.48

*Retail values estimated from average analyses obtained from tag sales and the comparative values established for 1934.

†Tonnage in these classes estimated on the basis of 200-pound bags or 10 bags per ton. All other classes estimated on the basis of 125-pound bags or 16 bags per ton. Cyanamid estimated on the basis of 100-pound bags or 20 bags per ton.

‡Not included in totals.

Table 10 gives the fertilizer tonnage for the spring and fall seasons as well as the total tonnage and estimated retail value for the year 1934.

Table 11 gives a summary of inspection on the basis of guaranteed and found composition and retail values, while Table 12 gives the standing of the manufacturers as determined by the inspection of 1934.

TABLE 11. Summary of Inspection on the Basis of Composition, Guaranteed, Found, and Retail Values

Class of Fertilizer	Number of Samples	Nitrogen (N), average per cent		Available phosphoric acid (P_2O_5), average per cent		Insoluble phosphoric acid (P_2O_5), average per cent		Total phosphoric acid (P_2O_5), average per cent		Potash (K_2O), soluble in water average per cent		Comparative value per ton dollars		Retail price per ton, average, dollars	Comparison, retail price and found comparative value per ton, dollars	Range in retail price per ton, dollars

*Dried Manure} Manufacturer not responsible for quality of nitrogen in these materials as they are inferior
†Muck } sources of nitrogen.

DEFINITION OF TERMS AND INTERPRETATION OF RESULTS ON FERTILIZERS AND LIMING MATERIALS ADOPTED BY THE ASSOCIATION OF OFFICIAL AGRICULTURAL CHEMISTS

NITROGEN

Acidulated fish tankage, acidulated fish scrap, is the rendered product derived from fish and treated with sulfuric acid.

Activated sewage products are made from sewage freed from grit and coarse solids and aerated after being inoculated with microorganisms. The resulting flocculated organic matter is withdrawn from the tanks, filtered with or without the aid of coagulants, dried, ground, and screened.

Charred peat is peat artificially dried at a temperature that causes partial decomposition.

Cyanamide and urea nitrogen is synthetic non-proteid organic nitrogen.

Crude, inert, or slow-acting nitrogenous materials are unprocessed organic substances relatively high in nitrogen but having a very low value as plant food and showing a low activity by both the alkaline and neutral permanganate methods (below fifty per cent [50%] and eighty per cent [80%] respectively).

Dried blood is the collected blood of slaughtered animals, dried and ground and containing not less than twelve per cent (12%) of nitrogen in organic forms.

Fish tankage, fish scrap, dry ground fish, fish meal fertilizer grade is the dried ground product derived from rendered or unrendered fish.

Garbage tankage is the rendered, dried and ground product derived from waste household food materials.

Hoof and horn meal is a product resulting from the processing, drying, and grinding of hoofs and horns.

Nitrate of soda is a commercial sodium nitrate containing not less than fifteen per cent (15%) of nitrogen, chiefly as sodium nitrate.

Peat is partly decayed vegetable matter of natural occurrence. It is composed chiefly of organic matter which contains some nitrogen of low activity.

Process tankages are products made under steam pressure from crude inert nitrogenous materials, with or without the use of acids, for the purpose of increasing the activity of the nitrogen. These products shall be called "Process Tankages" with or without further qualification. The water-insoluble nitrogen in these products shall test at least fifty per cent (50%) active by the alkaline, or eighty per cent (80%) by the neutral permanganate method.

Sheep manure-wool waste is the by-product from wool-carding establishments consisting chiefly of sheep manure, seeds, and wool fiber.

Sulfate of ammonia is a commercial product composed chiefly of ammonium sulphate. It shall contain not less than twenty and five-tenths per cent (20.5%) of nitrogen.

The term *tankage* (without qualification) shall be restricted to meat and bone tankage derived from the rendered, dried, and ground by-products from the slaughter of animals, or from carcasses of animals that have died otherwise than by slaughter.

PHOSPHORIC ACID

Ammoniated superphosphate is a product containing superphosphate and/or dissolved bone and nitrogenous compounds, but without the addition of potash.

Available phosphoric acid is the sum of the water-soluble and the citrate-soluble phosphoric acid.

"Basic" lime phosphate (lime based superphosphate) is a superphosphate to which liming materials have been added in a quantity at least six per cent (6%) calcium carbonate equivalents in excess of the quantity required to convert all water-soluble phosphate to the citrate-soluble form.

Basic phosphate slag is a by-product in the manufacture of steel from phosphatic iron ores. The product shall be finely ground and shall contain no admixture of materials other than what results in the original process of manufacture. It shall contain not less than twelve per cent (12%) of total phosphoric acid (P_2O_5), not less than eighty per cent (80%) of which shall be soluble in two per cent (2%) citric acid solution according to the Wagner method of analysis. Any other phosphate slag not conforming to this definition shall be designated low grade.

Citrate-soluble ("reverted") phosphoric acid is that part of the total phosphoric acid in a fertilizer that is insoluble in water but soluble in a solution of citrate of ammonia according to the method adopted by the A. O. A. C.

Definition of Products Secured by Heating Calcium Phosphate with Alkali Salts Containing Potash. These products are not potassium phosphate. They may be called non-acid phosphates with potash.

Dicalcium phosphate is a manufactured product consisting chiefly of a dicalcic salt of phosphoric acid.

Dissolved bone is defined as a ground bone or bone meal that has been treated with sulfuric acid.

Ground raw bone is a product resulting from drying and grinding animal bones that have not been previously steamed under pressure.

Ground steamed bone is a product resulting from grinding animal bones that have been previously steamed under pressure.

Mono-ammonium phosphate (fertilizer grade) is a commercial salt made by combining phosphoric acid with ammonia. It shall contain not less than ten per cent (10%) of nitrogen and not less than forty-six per cent (46%) of available phosphoric acid.

Phosphate rock is a natural rock containing one or more calcium phosphate minerals of sufficient purity and quantity as to permit its use, either directly or after concentration, in the manufacture of commercial products.

The term *phosphoric acid* designates (P_2O_5).

Precipitated bone phosphate is a by-product from the manufacture of glue from bones and is obtained by neutralizing the hydrochloric acid solution of processed bone with calcium hydroxide. The phosphoric acid is chiefly present as dicalcium phosphate.

Precipitated phosphate is a product consisting mainly of dicalcium phosphate obtained by neutralizing with calcium hydroxide the acid solution of either phosphate rock or processed bone.

Soft phosphate with colloidal clay is a very finely divided low-analysis by-product from mining Florida rock phosphate by a hydraulic process in which the colloidal materials settle at points in artificial ponds and basins farthest from the washer, and is later removed after the natural evaporation of the water.

Superphosphate is the product resulting from mixing rock phosphate and sulfuric acid and/or phosphoric acid. The grade should always be used as a prefix to the name. Example: 16% Superphosphate.

It is recommended that the use of the term "Acid Phosphate" be discontinued.

Uniformity in Use of Terms "Phosphoric Acid" and "Potash." As the terms phosphoric acid and potash are used universally in guaranteeing and in reporting the analyses of fertilizers, it is recommended that the same terms also be used in reporting and discussing the results of analyses of related materials.

POTASH

Kainit is a potash salt containing potassium and sodium chlorides and sometimes sulfate of magnesia with not less than twelve per cent (12%) of potash (K_2O).

Leached wood ashes are defined as ashes resulting from burning unleached wood, but as having had part of their plant food removed by artificial means or by exposure to rains, snows, or other solvent.

Manure salts shall be understood to mean potash salts containing high percentages of chloride and from twenty per cent (20%) to thirty per cent (30%) of potash (K_2O). The term double manure salts should be discontinued.

Muriate of potash is a potash salt containing not less than forty-eight per cent (48%) of potash (K_2O) chiefly as chlorides.

Nitrate of potash is a salt containing not less than twelve per cent (12%) of nitrogen and forty-four per cent (44%) of potash (K_2O).

The term *potash* designates potassium oxide (K_2O).

Sulfate of potash-magnesia is a potash salt containing not less than twenty-five per cent (25%) of potash (K_2O), nor less than twenty-five per cent (25%) of sulfate of magnesia, and not more than two and five-tenths per cent (2.5%) of chlorine.

Sulfate of potash is a potash salt containing not less than forty-eight per cent (48%) of potash (K_2O) chiefly as sulfate, and not more than two and one-half per cent (2.5%) of chlorine.

Unleached wood ashes are ashes that result from burning unleached wood, that have had no part of their plant food removed, and that contain four per cent (4%) or more of water-soluble potash (K_2O).

Ashes from leached wood are defined as unleached ashes resulting from burning wood that has been exposed to or digested in water or other liquid solvent, as in the extraction of dyes, so that a part of the plant food has been dissolved and removed.

LIMING MATERIALS

Agricultural liming material is any substance that contains calcium and magnesium in condition and quantity suitable for use in neutralizing soil acidity.

Air-slaked lime is the product obtained by exposing quicklime or hydrated lime to the atmosphere until partially carbonated.

Ground limestone is the product obtained by grinding either calcareous or dolomitic limestone. Not less than seventy-five per cent (75%) shall pass a 100-mesh sieve. It shall contain calcium and magnesium carbonate equivalent to not less than ninety per cent (90%) of calcium carbonate.

Ground shell marl is the product obtained by grinding natural deposits of shell marl. Not less than seventy-five per cent (75%) shall pass a 100-mesh sieve. It shall contain calcium and magnesium carbonates equivalent to not less than eighty per cent (80%) of calcium carbonate.

Hydrated or slaked lime is the product obtained by treating quicklime with sufficient water or steam to combine with its oxides.

Interpretation of the Word "Lime" as applied to Fertilizers. The term "lime" shall not be used in the registration, labeling, or guaranteeing of fertilizers or fertilizer materials unless the lime is in a form to neutralize soil acidity such as the oxide, hydroxide or carbonate, or equivalent magnesia compounds.

The word *lime* when applied to liming materials means either calcium oxide or calcium and magnesium oxides.

Quicklime, burned lime, caustic lime, lump lime, unslaked lime, are liming materials that have a high content of calcium oxide (with magnesium oxide) produced by heating suitable carbonates until substantially all of the carbon dioxide has been eliminated.

Waste lime, by-product lime, is any industrial waste or by-product containing calcium or calcium and magnesium in forms that will neutralize acids. It may be designated by the prefixation of the name of the industry or process by which it is produced, i. e., gas-house lime, tanners' lime, acetylene lime-waste, lime-kiln ashes, calcium silicate, etc.

FORMULA, GRADE, ANALYSIS, ETC.

The word *analysis*, as applied to fertilizers, shall designate the percentage composition of the product expressed in terms of nitrogen or ammonia, phosphoric acid, and potash in their various forms.

The term *fertilizer formula* shall be interpreted as expressing the quantity and grade of the crude stock materials used in making a fertilizer mixture. For example: 800 pounds of 16 per cent superphosphate, 800 pounds of 9-20 tankage, and 400 pounds of sulfate of potash-magnesia.

The grade of a fertilizer shall represent the minimum guarantee of its plant food expressed in terms of nitrogen, available phosphoric acid, and water-soluble potash.

The statement of guarantees of mixed fertilizers shall be given in whole numbers.

The *order of terms* in mixed fertilizers shall be nitrogen first, phosphoric acid second, and potash third.

BRAND AND BRAND NAME

A brand is a term, design, or trade mark used in connection with one or several grades of fertilizers.

A brand name is a specific designation applied to an individual fertilizer.

Interpretation of Brand Name to include the analysis or grade of fertilizer. The committee recommends and urges the practice of including the analysis or grade of fertilizer with the brand name, both by the manufacturer on sacks and in printed literature and by the control official in his reports and publications.

Significance of the Name of a Material used as the brand name or part of the brand name of a mixed fertilizer. When the name of a material is used as a part of the brand name of a mixed fertilizer, as for example blood, bone or fish, the nitrogen or phosphoric acid shall be derived from or supplied entirely by the material named. When the name of a material is used as a brand or as part of a brand and the nitrogen and phosphoric acid is not supplied by the material named, the word "brand" shall follow the name of the material. Example: "Fish Brand Fertilizer."

MISCELLANEOUS

Maximum Amount of Chlorine Permissible in Fertilizers in Which the Potash is Claimed as Sulfate. The chlorine in mixed fertilizers in which the potash is claimed as sulfate shall not exceed five-tenths of one per cent (0.5%) more than what is called for in the minimum potash content based on the definition for sulfate of potash as formulated by the committee. Calculate as follows: 0.05 times the percentage of potash found plus 0.5.

Dried pulverized or shredded manures shall be only what the name indicates, and not mixtures of manures and other materials.

The term *finely ground* in the definition of basic phosphate slag shall refer to actual size of particles as determined by the use of standard sieves, as follows: Seventy per cent (70%) or more should pass a 100-mesh sieve, and ninety per cent (90%), or more should pass a 50-mesh sieve.

Gypsum, land plaster, or crude calcium sulfate, are products consisting chiefly of calcium sulfate. They may contain twenty per cent (20%) of combined water. (They do not neutralize acid soils.)

Net Weights. The weights appearing on packages of fertilizer, agricultural lime, and liming material shall always mean net weights.

A unit of plant food is twenty (20) pounds, or one per cent (1%) of a ton.

Table 13 gives a detailed analysis of the individual official inspections for the year 1934.

TABLE 13. Report of Inspection of Fertilizer Collected in 1934

Swaim & Breeding	293a	1190	Edinburg	found	1.37			2.1	9.3	2.9		**5.5**

Where 60.0 per cent or more of the total nitrogen guaranteed was found to be water soluble, the active and inactive insoluble organic nitrogen was not determined.

Percentages appearing in bold type in the "Inactive water insoluble organic" column denote inferior nitrogen.

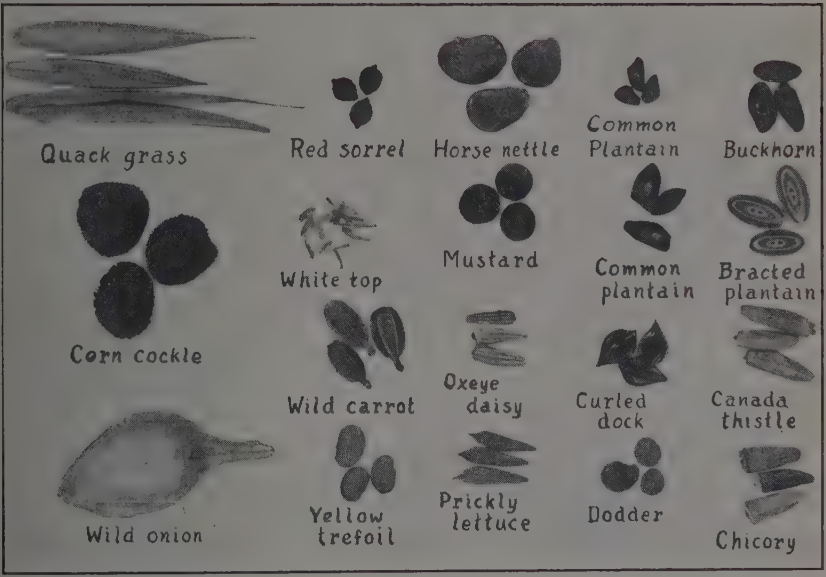
INSPECTION OF AGRICULTURAL SEEDS



Quack grass
Red sorrel
Horse nettle
Common Plantain
Buckhorn
Corn cockle
White top
Mustard
Common plantain
Bracted plantain
Wild carrot
Oxeye daisy
Curled dock
Canada thistle
Wild onion
Yellow trefoil
Prickly lettuce
Dodder
Chicory

The nineteen weed seeds designated as noxious in the Indiana Seed Law.

Agricultural Experiment Station
Purdue University
Lafayette, Indiana

Herein is presented a report of the Agricultural Seed inspection for the year from July 1, 1934, to June 30, 1935. The complete analyses of 1,085 official seed samples are given in detail. In addition 319 official samples drawn for test at the request of dealers and 2,937 free test samples of seed were tested during the year.

This circular also contains the Rulings of the State Seed Commissioner and discussions on free testing of seeds, directions for taking samples and directions for making germination tests at home.

Information is given to help the seedsmen in filling out the official Indiana State Seed Tag.

Violations of the Indiana Seed Law and of the Federal Seed Act are discussed together with helpful suggestions to seed dealers and seed purchasers.

Table 1 shows the progress in seed inspection.

Tables 2, 3 and 4 give the average analysis of the official samples in the years 1922, 1934 and 1935 respectively.

Tables 5 and 6 state the percentage of samples of red clover, alfalfa, sweet clover, alsike clover, timothy and Korean lespedeza containing each of the noxious weed seeds.

Table 7 gives the names and addresses of the seedsmen whose seeds were sampled and tested during the past year and the number of samples classified as technically misbranded and seriously misbranded.

Table 8 shows in detail the results of the analyses of 1,085 official samples.

INSPECTION OF AGRICULTURAL SEEDS

H. R. KRAYBILL, *State Seed Commissioner*
P. B. CURTIS, *Associate Chemist*
O. S. ROBERTS, *Chief Inspector.* REGINA B. SCHULTE,* *Seed Analyst*
Assistant Seed Analysts: PAULINE BALBACH, MARY E. GREY
Inspectors: C. M. COHEE, J. W. JACKMAN

The Indiana Seed Law is an Act to regulate the sale of and commerce in agricultural seeds. It requires every lot, package, bag or bulk lot of seed containing one pound or more which is sold, offered or exposed for sale within the state for seeding purposes to be tagged with official Indiana State Seed Tags. These tags must carry the name and address of the vendor of the seed, a statement of the minimum percentages of purity and germination and the maximum number per pound of each of the weed seeds which are listed as noxious under the law. The date of the germination test and state or foreign country in which the seed was grown must also be designated.

The Indiana Seed Law also provides for inspection and testing of samples of seed to determine whether or not the statements of the seedsmen on the tags are correct. This requires the services of Inspectors who travel over the State and secure samples of seed from seed dealers, seed stores and seed purchasers. Inspection samples are drawn with specially designed samplers so as to obtain a representative sample from each lot and these samples are then forwarded to the seed laboratory of the State Seed Commissioner where they are tested.

Results of Inspection

During the year from July 1, 1934, to June 30, 1935, 1,404 samples were collected in all sections of the state. Complete tests of these samples were made and reports were sent to the distributors, dealers and consumers from whom the samples were secured. In addition 2,937 free test samples and 116 Custom House samples were analyzed. The testing of all of these samples entailed the making of 3,258 purity tests, 17,912 individual germination tests, 87 examinations and 97 identifications. Of the 1,404 official samples, 319 of them were drawn and tested upon request of seedsmen in order that they might know the percentages of purity and germination and the number per pound of noxious weed seeds to list on their tags. Of the remaining 1,085 samples, 196 of them were found to be seriously misbranded. This represents 18.1 per cent of the samples as compared to 14.0 per cent in the preceding year. This increase in percentage of samples seriously misbranded may have been due to the abnormal high seed prices and scarcity of seed which tempted the unscrupulous seedsmen to misrepresent their seed.

Tolerances

Under the most perfect and approved conditions of testing seeds, variations will occur in purity and germination tests. For this reason the Association of Official Seed Analysts, whose methods of testing are followed in this seed laboratory, has adopted tolerances or allowances for purity and germination tests. Samples of seed with a claim within the tolerances are not considered to be misbranded under the provisions of the Indiana Seed Law, but seed dealers are expected to change the claim on the tags of the unsold portion to correspond to the analysis found by the Seed Commissioner.

---

* Assistant Botanist, in cooperation with the Division of Seed Investigations, Bureau of Plant Industry, U. S. D. A.

(a) Purity Tolerance.—In determining the tolerance for purity the sample shall be considered as being composed of two parts: (1) pure seed of the kind certified and (2) everything not pure seed. The tolerance permitted shall be two-tenths of 1 per cent (0.2%) plus 20 per cent of the lesser part. Example: Seed marked 98 per cent pure, the lesser part is 100 minus 98 or 2. Twenty per cent of 2 equals 0.4. Therefore, the tolerance allowed would be 0.2 plus 0.4, or 0.6%.

(b) Germination Tolerance.—A larger and more arbitrary tolerance is applied between a given germination and the result of the germination test as follows:

Given Germination (Per Cent)	Allowable Variation (Per Cent)
90 or over	6
80 or over but less than 90	7
70 or over but less than 80	8
60 or over but less than 70	9
Less than 60	10

Rulings of the State Seed Commissioner

In accordance with the provisions of the Indiana Seed Law empowering the Seed Commissioner to prescribe and enforce such rules and regulations as he may deem necessary to carry into effect the full intent and meaning of the Act the following rulings have been made:

Ruling No. 1. Hard Seeds. The phrase "minimum percentage of germination," as contained in the Indiana Seed Law, is interpreted to mean the actual percentage of the seeds that sprout or germinate at the end of the time usually allowed for germination test. In the case of leguminous seeds containing "hard seeds," the actual percentage of germination should be given on the official label and this germination percentage may be followed by the percentage of hard seeds. For example, the seed showed 85 per cent actual germination and in addition contained 10 per cent hard seeds. This may be stated on the label as 85 per cent germination and 10 per cent hard seeds. This cannot be stated as 95 per cent germination and 10 per cent hard seeds.

Ruling No. 2. Tagging. All agricultural seed in condition for seeding purposes shipped or delivered in the State of Indiana must have attached to each bag or package of one pound or more an Indiana State Label properly filled out.

The wholesale seedsman is required to attach at least one Indiana state tag properly filled out to each package of one pound or more of seed shipped to the retail seedsman. The retail seedsman is then required to attach sufficient tags to the seed to cover its net weight before offering or exposing the seed for sale. If the seed is shipped directly to the consumer, sufficient Indiana state tags must be attached to cover the net weight of the seed.

Farmers' Exemption

A farmer is exempt from the provisions of the seed law when the seed is grown, sold and delivered by that farmer on his own premises to the purchaser himself. If, however, the seed is advertised for sale by the public press, circular or catalogue, or if the seed is delivered by a common carrier, the farmer is considered as a vendor and must comply with the provisions of the Act. Seed taken to community sales for sale must be labeled in accordance with the law.

Free Testing of Seeds

During the past year 2,937 samples of seed were tested free of charge for farmers and seedsmen. The privilege of having these tests made is one of much value to the farmer and the smaller seed dealers who do not have facilities for testing seeds. Not all of the tests requested can be made promptly during the busy season from January to March. Therefore it is important that all samples be sent in as early as possible preferably from September to December. When submitting a sample of seed for test to the seed laboratory the following directions for securing the sample should be observed in order that the sample may represent as accurately as possible the lot from which it is taken.

Directions for Taking Samples

1. The minimum weight of seed forwarded for test should be approximately:
    - (a) Two ounces (cupful) of grass seed of any kind or of white and alsike clover;
    - (b) Five ounces (cupful) of red and crimson clover, alfalfa, millet, flax or seed of like size;
    - (c) One pound (pint) of cereals or seed of like size.
2. Samples may be drawn:
    - (a) With seed triers;
    - (b) With long stickers;
    - (c) By hand, taking approximately equal parts of the sample from at least three different places in the sacks, including the top and opposite sides as near the bottom as practicable.
3. Samples should be drawn from each bag when there are not more than five bags in the lot, from every fifth bag when there are more than five bags, but never from less than five bags. All samples so drawn are combined into one composite sample.

Directions for Making Germination Tests at Home

Satisfactory germination tests may be made of the larger field seeds at home, leaving the laboratory facilities of the Agricultural Experiment Station available for the grasses and clovers which are more difficult to analyze.

The seed to be germinated should be mixed thoroughly and the required number of seeds (100 seeds of grains and 200 of clovers and other small seeds) counted out just as they come.

The plate germinator is satisfactory and very simple to operate. The seeds to be germinated are placed between two thicknesses of folded blotting paper or cloth (heavy grade of muslin or canton flannel). This should be moistened and placed between ordinary tin or porcelain plates and kept in a warm room where the range in temperature is from approximately 85 degrees during the day to 65 degrees at night. The place selected for the test should not be too near a window, stove or register.

The time required for germination tests varies with different kinds of seed. Under favorable conditions grass and clover seeds begin to sprout in three or four days. The tests should be continued for ten days or two weeks. Every two days the tests should be examined and a record made of the number of seeds that have sprouted. Also the blotting paper or cloth must be kept sufficiently moist. The number of seeds which germinate out of the 100 seeds will give the percentage of germination. However, those seeds which develop weak sprouts should not be counted because they may not continue their development into normal plants.

Filling Out Official Indiana Labels

Purity

The minimum purity means the percentage of pure seed of the kind and variety given on the official label. Statements of purity, as 97 per cent including 2 per cent crop seeds, or 95 per cent and 2 per cent crop seeds, will not be permitted. In cases where the seed contains two or more kinds of agricultural seed, each present in excess of 5 per cent, the seed mixture should be labeled with the official green colored mixture labels, Style C.

The filling out of the column "per cent of seed" on the mixture labels can be explained best by an example. For instance if a mixture is composed of 60 per cent Kentucky Blue Grass with a purity of 80 per cent and 40 per cent of Red Top with a purity of 90 per cent, the per cent of Blue Grass should be given as 48 per cent, obtained by taking 80 per cent of 60. The Red Top should be given as 36 per cent, obtained by taking 90 per cent of 40.

The percentage of purity on the large seeds such as soybeans, corn, wheat, vegetable seeds, etc., must be stated on the official label the same as on any other seed.

Germination

The term minimum germination means the percentage of sprouts obtained in the prescribed time for the test. If the seed contains hard seeds this percentage should be stated after the term "hard seed" on the official label. In no case should the sum of the percentages of sprouts and hard seeds be given as the percentage of minimum germination.

Distributors should not ship seed until the germination test is completed. The statement "In Test" on the official label does not meet the provisions of the seed law. If there is a demand for the seed the dealer may be tempted to sell the seed before he receives a report on the germination, thus placing himself liable to prosecution.

Noxious Weed Seeds

The number per pound of each of the noxious weed seeds present must be listed on the reverse side of the tag irrespective of the number present. The term "trace" is not permissible. The statement of the noxious weed seeds in terms of per cent or in terms of proportion will not be permitted.

Place Where Grown

The official tag must give the name of the state, territory or foreign country where the seed was grown. Terms such as Domestic, U. S. A., Northwestern, and Central States do not meet the requirements of the law, and seed found so labeled will be immediately removed from sale until the tags have been corrected.

Certified, Verified and Affidavit Seed

Certified seed is seed the purity, germination, and variety of which is certified to by some state certifying agency or an agency closely associated with some state office or department. The seed is shipped in sealed sacks with a certified seed tag attached. During the growing season the fields are inspected to ascertain trueness to variety of crop, and after the harvest the seed is tested to determine whether it meets the prescribed standards of the certifying agency. In Indiana the Indiana Corn Growers' Association certifies corn, wheat, oats, lespedeza and soybeans. The other most commonly certified seed found in the state is Grimm alfalfa.

Verified-Origin seed is seed the origin of which is attested to by certain government approved seed dealers. Seed verification service deals with origin only, meaning Place Where Grown, and gives no guarantee as to the variety, purity or viability of the seed. At the present time red clover and alfalfa are the only seeds verified as to origin. Verified seed is tagged with tags bearing the official verification emblem.

Affidavit Grimm is alfalfa seed for which the grower has made affidavit as to its being Grimm Alfalfa. This affidavit seed is not regulated by either State or Federal Government.

Violations of the Law

Violations of the Indiana Seed Law may be divided into two classes: first where the seed is sold or offered for sale without official Indiana State Seed Tags, and second where the seed is tagged but fails to meet the certifier's claim stated on the tags. In both of these cases shipments or lots of seed were removed from sale until proper tags had been attached to cover the seed in question.

During the past year three cases of misbranding and one case of non-tagging were called to the attention of prosecuting attorneys. All of these cases resulted in convictions and payment of fines. Furthermore, under the Interstate Clause (Sec. 6) of the Federal Seed Act seventeen cases were reported to the Division of Seed Investigations of the Bureau of Plant Industry of the United States Department of Agriculture.

The following are excerpts from publications concerning the disposition of previous seed cases submitted.

Prosecutions Under the Interstate Clause (Sec. 6) of the Federal Seed Act July 1, 1933, to June 30, 1934.

16. Misbranding of red clover seed. U. S. & Market Gardeners' Seed Company. Plea of guilty. Fine $200. (F.S.50).

Kind and amount of seed: Red clover, two bags (335 pounds).

Shipped by Market Gardeners' Seed Company, Cincinnati, Ohio, February 9, 1932.

From Cincinnati, Ohio, to Versailles, Indiana.

Action taken: Information was filed in the United States District Court for the Southern District of Ohio alleging that the Market Gardeners' Seed Company, a corporation, unlawfully delivered for transportation in interstate commerce the above-mentioned shipment, misbranded in violation of the Federal Seed Act in that it was labeled in part "minimum pure seed 94.2—4.8 crop —99.0% Min. Germination—90%", whereas the seed "did consist of pure cloverseed in a proportion less than 94.2%" and germinated "not more than 72.25%". The seed was found to be 90.08 per cent pure seed and to contain 3.46 per cent of weed seeds.

Disposition: On June 13, 1932, the defendant entered a plea of guilty and was fined $200.

17. Misbranding of sweet clover seed. U. S. & Berry Seed Company. Plea of guilty. (F. S. 51.)

Kind and amount of seed: Sweet clover, one bag (90 pounds).

Shipped by Berry Seed Company, Clarinda, Iowa, March 9, 1932.

From Chicago, Illinois, to New Albany, Indiana.

Action taken: Information was filed in the United States District Court for the Northern District of Illinois alleging that the Berry Seed Company, a corporation having a place of business in Clarinda, Iowa, and also in Chicago, Illinois, unlawfully delivered for transportation in interstate commerce the above-mentioned shipment, misbranded in violation of the Federal Seed Act in that it was labeled in part "Germ. 92%", whereas the seed germinated "not more than 44.25%".

Disposition: On December 13, 1933, the manager of the American Field Seed Company, Chicago, Illinois (reported to be a subsidiary of the Berry Seed Company), entered a plea of guilty. The case was then combined with three others against the same defendant, and a fine of $200 was imposed. (See Nos. 18, 19, and 29.)

18. Misbranding of sweet clover seed. U. S. & Berry Seed Company. Plea of guilty. (F. S. 52.)

Kind and amount of seed: Sweet clover, one bag (60 pounds).

Shipped by Berry Seed Company, Clarinda, Iowa, February 16, 1932.

From Chicago, Illinois, to Solsberry, Indiana.

Action taken: Information was filed in the United States District Court for the Northern District of Illinois alleging that the Berry Seed Company, a corporation having a place of business in Clarinda, Iowa, and also in Chicago, Illinois, unlawfully delivered for transportation in interstate commerce the above-mentioned shipment, misbranded in violation of the Federal Seed Act in that it was labeled in part "Germ. 92%", whereas the seed germinated "not more than 44.5 per cent".

Disposition: On December 13, 1933, the manager of the American Field Seed Company, Chicago, Illinois (reported to be a subsidiary of the Berry Seed Company), entered a plea of guilty. The case was then combined with three others against the same defendant, and a fine of $200 was imposed. (See Nos. 17, 19 and 29.)

29. Misbranding of sweet clover seed. U. S. & Berry Seed Company. Plea of guilty. (F. S. 88.)

Kind and amount of seed: white sweet clover, two bags (240 pounds).

Shipped by Berry Seed Company, Clarinda, Iowa, March 13, 1933.

From Chicago, Illinois, to Thorntown, Indiana.

Action taken: On August 25, 1933, information was filed with the United States District Court for the Northern District of Illinois alleging that the Berry Seed Company, a corporation with a place of business in Clarinda, Iowa, and also in Chicago, Illinois, did unlawfully deliver for transportation in interstate commerce the above-mentioned shipment of seed misbranded in violation of the Federal Seed Act in that it was labeled in part "Purity 97.5%, Germ. 88%", whereas the seed had a purity of "less than 97.5%" and germinated "much less than 88%".

Disposition: On December 13, 1933, the manager of the American Field Seed Company, Chicago, Illinois (reported to be a subsidiary of the Berry Seed Company), entered a plea of guilty. The case was then combined with three others against the same defendant, and a fine of $200 was imposed. (See Nos. 17, 18 and 19.)

Attention Distributors and Dealers

If seeds such as oats and soybeans are sold for seeding purposes they come under the provisions of the law and must be tagged with Indiana seed tags. It is not proper for the dealer to say that he is selling his oats or soybeans as feed oats or feed soybeans and thereby attempt to evade the seed law when these seeds are actually being sold for seeding purposes. The mere fact that the dealer says that he is selling his oats and soybeans as feed when it is generally known and he himself as well knows that they are going to be used for seed does not in any way relieve him from the responsibility of complying with the seed law by properly tagging the oats and soybeans with official Indiana Seed Tags.

Attention Purchasers

The seed buyer should insist that the seed be properly labeled and report any irregularities to the State Seed Commissioner. All tags, correspondence and records pertaining to seed purchases should be saved until the buyer is satisfied that the seed he received has met the desired qualifications. If the case appears to violate the Federal Seed Act the State Seed Commissioner may report the matter to the United States Department of Agriculture.

The Indiana Seed Law does not prohibit the sale of inferior seed when such seed is tagged correctly. For this reason the purchaser should always read the information stated on the tag before buying his seed. Failure to purchase good quality labeled seed may result in poor stands, undesirable varieties and infestation of the soil with noxious weed seeds.

The farmer should make it a rule to buy his seed from a reliable dealer, remembering that poor seed is dear at any price and that quality and not price should be the chief consideration. Table 7 entitled "Summary of Seed Inspection, July 1, 1934, to June 30, 1935" may be of considerable value to seed purchasers in that it shows just how careful the different seedsmen were in tagging their seeds and also in maintaining the claims on their tags.

Table 1 shows that in general there has been a continued improvement in the correct labeling of seeds in the last few years.

Examination of Tables 2, 3 and 4 also shows a marked improvement in the quality of the seed offered for sale but the quality of much of the seed could be increased a great deal by more thorough cleaning. Tables 5 and 6 showing the percentages of official samples of red clover, alfalfa, sweet clover, alsike, clover, timothy and Korean lespedeza which contained each of the noxious weed seeds further demonstrate the need for more efficient removal of the noxious weed seeds.

Table 8 gives in detail the results of the analyses of 1,085 official samples.

Table 1—Progress in Seed Inspection

Year	Number of Samples Examined	Number Seriously Misbranded	Per Cent Seriously Misbranded
1925	745	271	36.4
1928	969	289	29.6

ELECTRICITY SERVES THE FARM HOUSEHOLD

Gail M. Redfield, *Department of Home Economics*
Truman E. Hienton, *Department of Agricultural Engineering*

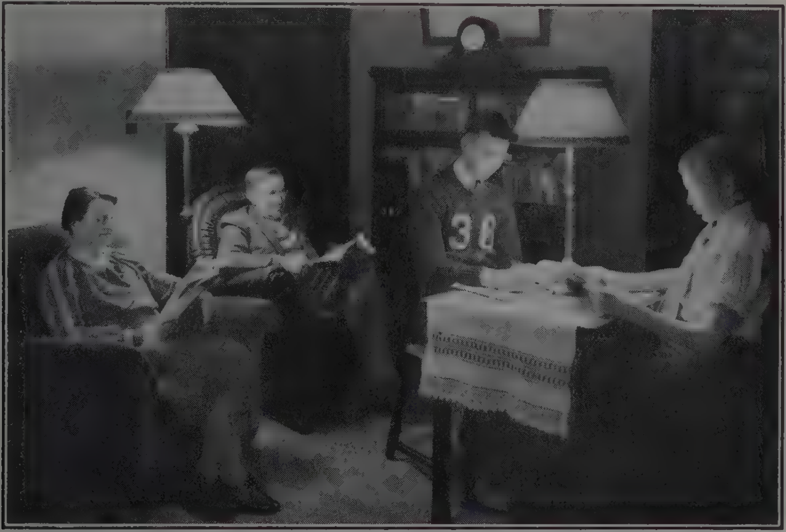

Figure 1. Lamps of proper design provide adequate light at low cost.

The two reading lamps used in this Tipton County farm home are designed to provide adequate light and eliminate glare. A lamp of this type will consume one kilowatt-hour in ten hours and will cost from one-half to three-fourths of a cent per hour for electricity.

Electricity lightens the work of the homemakers on more than 35,000 Indiana farms and, with the constantly increasing spread of rural electric lines, will do the same for many others in the future. As a source of light, heat and power, electricity has become an indispensable servant to homemakers in making their farm homes more livable and their care less laborious.

Extension of electric service and the adoption of electric equipment has taken place largely during the past decade. Results of a survey of 496 Indiana electrified farms by the Agricultural Experiment Station in 1925 revealed that electricity was employed very sparingly in the household, frequently only for lighting purposes. The situation at that time stimulated the initiation of studies on electric household equipment on Indiana farms by the Agricultural Experiment Station. Many different articles of equipment were installed under its direction in the houses of the experimental farms near Bedford and Wanatah and in those of six co-operators on the Pinney-Purdue experimental electric line in LaPorte County. Each article was individually metered and its electric consumption recorded monthly for a period of three years. Additional data were obtained for a period of one year by individual metering of equipment in 49 farm households located in the following counties: Allen, Bartholomew, Clinton, Delaware, Elkhart, Fountain, Grant, Hamilton, Howard, Marion, St. Joseph, Vanderburg, Vigo, Wabash and Wells.

Illumination of the house has been the first thought for using electricity in the past, but other applications, such as the radio and pump, are now considered just as important. Electric power for pumping water for household uses, running the refrigerator, operating the vacuum cleaner, and other small motor-driven equipment is desired by farm homemakers. Electric heat for the iron or ironer, for cooking food, heating water, and other appliances likewise is of interest to them.

Lighting

Good lighting probably contributes more than any other single item to the comfort and happiness of the farm family. It is used by every member of the family several hours every day during a large portion of the year. Records of electric consumption on 56 Indiana farms for 1934 indicate that electricity used for lighting averages from 10 to 20 kilowatt-hours per month throughout the year.

Adequate lighting equipment gives good light at all work, study and reading centers and is so shaded that there is no glare. Special, as well as general lighting, should be provided in practically all rooms. A single center fixture in the kitchen gives a general light to the rooms, but at most work centers, such as the sink or range, the homemaker's shadow frequently obscures her work. Separate fixtures should be provided to care for these work centers when necessary. Similarly, in the living room, additional light should be provided at the desk or table and near each reading center. Light at these places is usually provided by portable lamps.

Attractive lamp shades add to the decorative scheme of any room but should be selected primarily from the standpoint of efficiency. Lamps are available which are especially designed for reading such as those shown in Figure 1. These lamps are designed to give adequate and efficient light and safeguard the eyes.

Water Supply

Electric motors provide a convenient and economical source of power for pumping water. Many forms of power may be used to drive the pump but none are as easy to control automatically nor usually as economical to operate as the electric. Studies for an entire year on five Indiana farms reveal that an average of 2.1 kilowatt-hours were consumed per month by shallow-well pumps to furnish all the water used in the house including bathroom and kitchen sink. On four other farms, where two deep-well and two shallow-well pumps were installed, the energy consumption for pumping water used on the entire farm, as well as in the household, averaged 6.2 kilowatt-hours per month for the year.

Running water eliminates labor in pumping and saves many steps required in carrying water from the cistern or well to the kitchen. It also makes the use of a sink more convenient and furnishes the supply required for the installation of a bathroom. Pressure systems are often installed and operated by hand or other power. The substitution of an electric motor as the power unit is a simple matter when electric service becomes available.

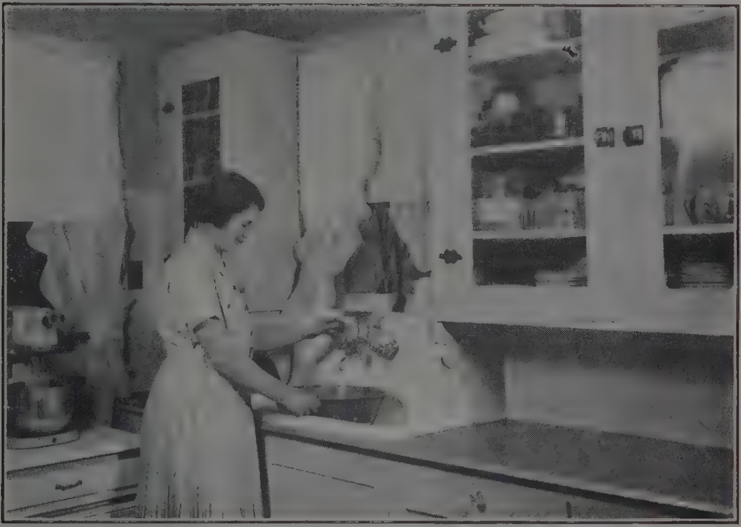

Figure 2. Running water is provided automatically by electric pumps for a few cents per month for power.

Water under pressure eliminates endless steps and labor spent in pumping and carrying it on this farm in Delaware County. On five Indiana farms, 2.1 kilowatt-hours were used per month by automatic shallow-well pumps to provide water for the household.

Laundry

Laundry work is one of the hardest jobs in the average farm home due largely to the lack of adequate equipment and facilities. The washing and ironing must be done at least once a week and it is work that needs and deserves good equipment.

The electric washer not only cuts down much of the hard labor involved in washing but also reduces the time required. Studies have shown that time consumed with an electric machine is about one-third that required with the washboard and one-half that with hand-power equipment.

An electric washer uses very little electricity. Records obtained for a year, for washing in 13 Indiana farm homes, show an average consumption of 2.32 kilowatt-hours per month. The amount used varied from 0.5 kilowatt-hour in a family of two to 4.0 kilowatt-hours in two larger families. A portable or small stationary motor may be attached to a hand-power washer to convert it into an electrically driven machine.

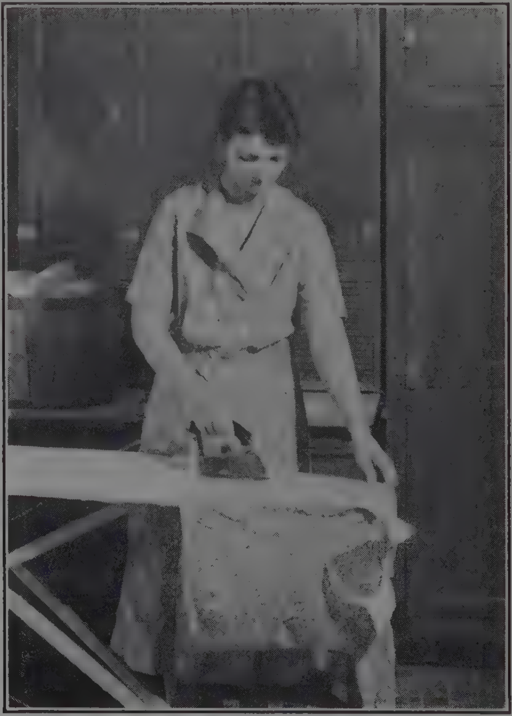

Figure 3. The electric iron is one of the first electrical appliances purchased after electric service is obtained.

The ironing can be done with an electric iron in two-thirds the time required with the use of sadirons. According to records obtained in Indiana farm homes, irons consume an average of 4.6 kilowatt-hours per month. The large sole plate of this new light-weight, high-wattage iron aids this Delaware County farm housewife in reducing the time and energy expended in ironing.

The electric iron is often the first single piece of equipment secured for use in homes after electricity has been obtained. It saves time and energy, is convenient, and has both low initial and operating costs. Records kept for the Agricultural Experiment Station show that the electric hand iron uses an average of 4.6 kilowatt-hours per month with a range in consumption from 1.7 to 6.3 kilowatt-hours. Many irons, now being manufactured, are light in weight, have large sole plates and automatic temperature controls. These features reduce the time and energy required for ironing. Studies have shown that the ironing can be done in about one-third less time with an electric iron than with sadirons.

An ironer is useful where there are large amounts of ironing to be done and can be used for practically the whole ironing at a saving of at least half the time required with the electric hand iron. It will use an average of 14.0 kilowatt-hours per month according to records obtained in five Indiana farm homes. There are two general types of ironers, the rotary type and the press type, both of which have been found satisfactory. The temperature of the shoe is automatically controlled on many ironers, usually by a separate control for each end. On some models, the temperature must be controlled by the operator.

Water Heating

Heating an adequate supply of water for household use is an important problem on the farm. The modern electric water heater is attractive in appearance and may be placed in any convenient location. It is entirely indepen-

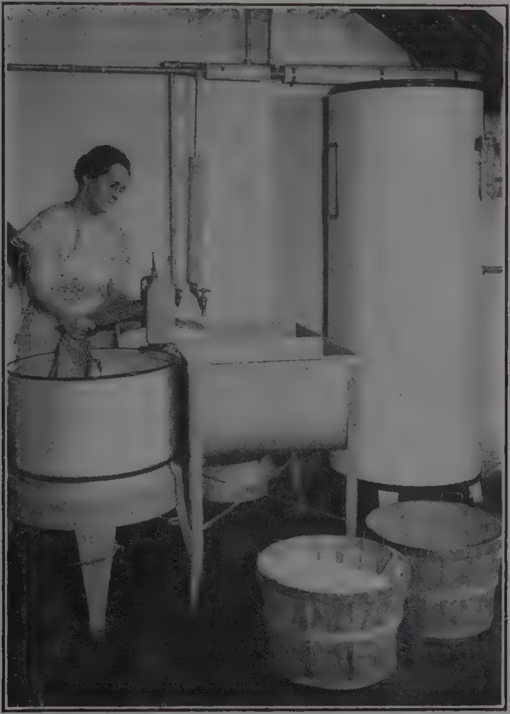

Figure 4. Full-automatic electric water heaters furnish a constant supply of hot water for the laundry, kitchen and bathroom.

On this farm near Selma, the electric washing machine, running water and automatic electric water heater minimize washday labors. Special water heater rates make the cost for hot water approximately ten cents a day. Washing machines use one-half kilowatt-hour per week.

dent of any fire, does not require a chimney, and demands practically no attention. The proper connection to an electric outlet and the ordinary piping connections for both hot and cold water are all that are necessary for its installation. A special circuit is required for a water heater but, if 110-220 volt service is available in the house, the necessary wiring for the water heater can be installed at very little cost.

Water heating rates are available from 1.0 to 1.3 cents per kilowatt-hour for 24-hour operation in practically all sections of Indiana. Special off-peak water heating rates are available in some sections of the state and, in this class of service, water is heated only during certain specified hours, usually during the night. Five household water heater installations of the full-automatic type used an average of 254.3 kilowatt-hours per month on Indiana farms. Good insulation of the water-storage tank is essential to efficient operation.

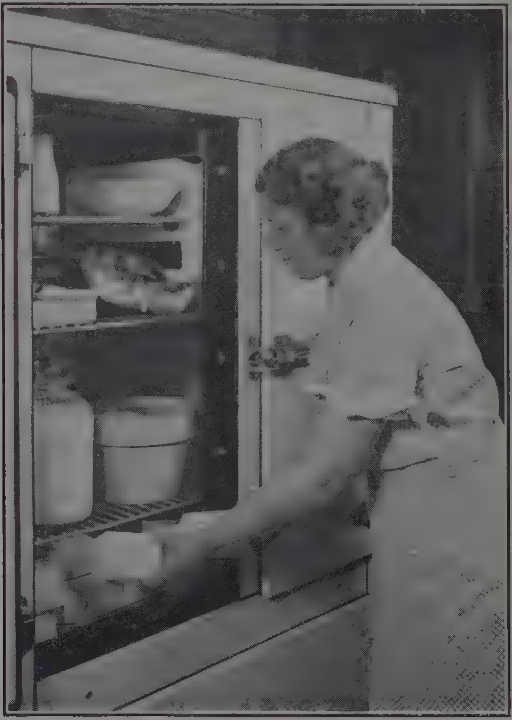

Figure 5. Electric refrigerators preserve farm produce in good condition for table use or sale.

This large electric refrigerator in a Delaware County home, like many others in the state, is used for the storage of both household foods and marketable produce. Household refrigerators on Indiana farms use an average of 48.0 kilowatt-hours per month when operated the entire year.

Refrigeration

The procurement of adequate refrigeration, which is necessary for the proper storage of foods, is one of the biggest problems in the average farm home. This is seldom possible without some type of mechanical refrigeration due to difficulty in obtaining satisfactory ice service. Thirteen electric refrigerators in farm households used an average of 48.0 kilowatt-hours a month, when operated throughout the year, according to records kept for a year on Indiana farms. The average consumption per month varied from 33.9 to 63.3 kilowatt-hours. Four others, used by small families, were operated only during the summer months and averaged 45.1 kilowatt-hours. The capacities of the refrigerator cabinets included were four of 5 cubic feet, three each of 4, 6 and 7 cubic feet, and one each of 5½, 9, 11 and 12 cubic feet.

A recent survey of 144 mechanical refrigerators, in use on Indiana farms, disclosed the fact that 36 or 25 per cent were used partially for the storage of marketable produce. An example of this use of a refrigerator on a Delaware County farm is shown in Figure 5. Marketable produce, such as butter, eggs, cream, poultry, fresh fruits and vegetables, is stored as well as freshly butchered meats which are held in the refrigerator until used.

This survey also showed that the average capacity of refrigerators, in which marketable produce is stored, is 6.86 cubic feet and 6.29 cubic feet for refrigerators used only for storing household foods. Of the refrigerators in which marketable produce is stored, 84.8 per cent are operated the entire year while only 60.4 per cent of the others are operated for the same time.

The degree of satisfaction, which any user will get from her refrigerator, will depend on how it is used. Proper operation, which insures the best results, includes a study of the best placing of foods in the refrigerator. Liquids and moist foods should always be covered, and all foods should be cooled to room temperature before they are put into the refrigerator for the greatest economy in operation.

Cooking

Electric energy for cooking is safe, clean and efficient and is becoming more popular in rural Indiana homes with the decrease in electric rates and recent improvements in electric ranges. Cooking rates are available at 2½ to 3 cents per kilowatt-hour in most localities in the state. These rates make electricity compare very favorably in cost with fuels in common use. Records kept for a year on the energy consumption for cooking in 20 Indiana farm homes showed an average of 116.6 kilowatt-hours per month, varying from 53.0 in a family of two to 318.5 in a family of eleven.

Energy is consumed by an electric range only while cooking is actually in progress and is conserved by the thermostatic control when the oven is used. The insulation in the oven of an electric range reduces the heat lost, thus making the kitchen more comfortable during the summer months. Combination coal or wood and electric ranges are often used where there is no heat other than that supplied by the range to provide the necessary heat for the kitchen during cold weather. Records show that when electricity is used for cooking the time required in the care and cleaning of the range is only 26 minutes a week. An average of three hours and two minutes a

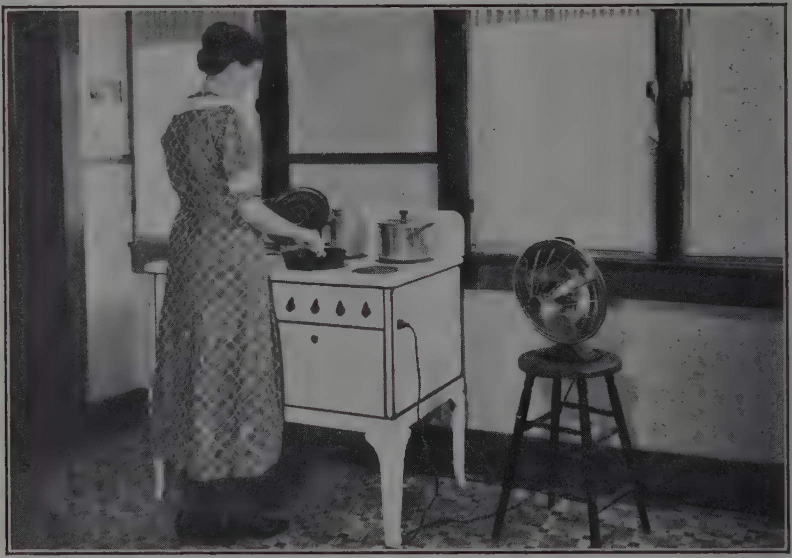

Figure 6. Electricity for cooking is appreciated in the farm home for its safety, convenience and time saving.

Records obtained in Indiana farm homes show that electricity used for cooking averages four kilowatt-hours per day. An electric heater furnishes auxiliary heat, when it is needed, to maintain a comfortable temperature in a kitchen like this one in Howard County which has no furnace outlet.

week was spent by the homemaker in kindling fires, carrying fuel, removing ashes, and cleaning stoves with wood and coal ranges.*

The homemaker largely controls the amount of electric energy used for cooking by her care in handling the equipment. Two identical ranges, on which records were obtained in one locality in Indiana, were operated by women cooking for the same size families. One woman used an average of 58.1 kilowatt-hours per month while the other used 97.3 kilowatt-hours.

Radio

The radio has probably done more to eliminate the isolation of the farm home than any other single article and is considered by many farm people as a necessity. Recent figures show that 32 per cent of Indiana farms are equipped with radios. There is no other agency which provides in one instrument the same variety of information and entertainment as does the radio. It furnishes the latest news, programs of interest to the homemaker and facts to assist the farmer in planning his field work, and market reports to help in disposing of farm produce.

Radios operated directly from electric outlets use from 50 to 100 watts, or one kilowatt-hour in 10 to 20 hours. They are available for either 110- or 32-volt circuits. The operation from a lighting circuit eliminates the necessity for keeping a storage battery charged and the purchase of dry cells.

---

*Bul. No. 339 Fuels Used for Cooking Purposes in Indiana Rural Homes.

Cleaning

Cleaner rooms result from the use of a vacuum cleaner and the labor and time involved in cleaning a house are considerably less than with a broom. Special attachments are available for a cleaner, operated by the same motor, for cleaning upholstered furniture, draperies, mattresses, pillows and the interior of automobiles. Small hand machines are also available for this type of cleaning. A vacuum cleaner has a small motor and operates at a very low cost. Records in three Indiana farm homes for a year show an average use of 1.8 kilowatt-hour per year, with a variation from 1.5 to 2.1.

Small Heating Appliances

The electric toaster is used in farm homes because of its low first cost and practically daily demands. A more desirable product can be obtained using a toaster at the table than when using any one of the old types on the range. A regular toaster is less expensive to operate than either a surface unit toaster or the oven of an electric range. Many toasters are automatic, so bread toasted the exact amount desired by each member of the family is obtained at the table with little attention on the part of the homemaker. In the average family, a toaster uses about four kilowatt-hours per month.

Waffle irons offer many variations to the menu for, in addition to plain waffles, ginger bread, cakes and fritters can be baked on them. The waffle iron can be used at the table to prepare the main part of any meal, the

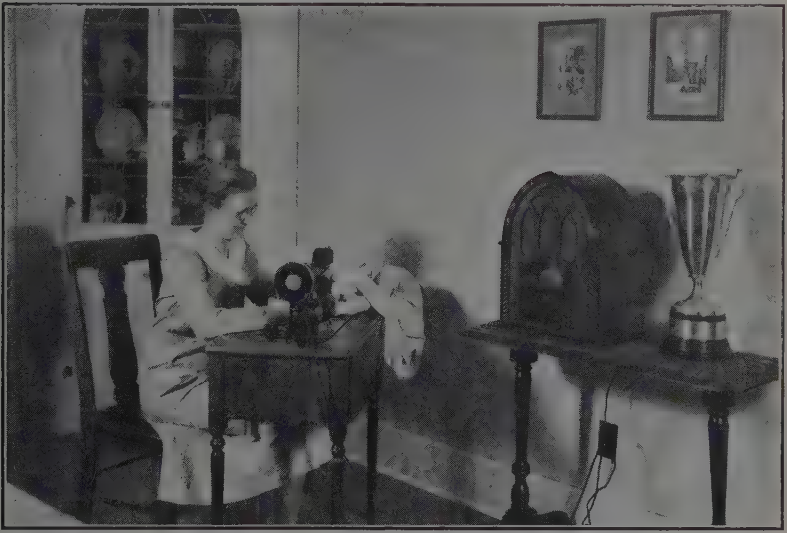

Figure 7. Radios lessen the isolation of the farm family for less than half a cent an hour spent for electricity.

Varied entertainment and educational programs are available at any hour. This Delaware County homemaker enjoys these while she sews for her family. The sewing machine uses less than one kilowatt-hour a month for its operation.

dessert, or the Sunday night supper. Uniform products result from the use of the automatic type waffle iron. Approximately 0.1 kilowatt-hour per person is consumed by the waffle iron each time it is used.

Consumption of electric energy by coffee makers and percolators varies with the wattage of the heating element and the amount of use of the equipment. The most common types will operate one and one-half hours on one kilowatt-hour. Other small electrically heated appliances in use in farm homes include the hot plate or table stove, room heater, egg cooker, well-type cooker, portable electric oven, tea kettle and small immersion type water heater. These last mentioned electric cooking devices are used very frequently as auxiliary appliances in homes that do not have an electric range.

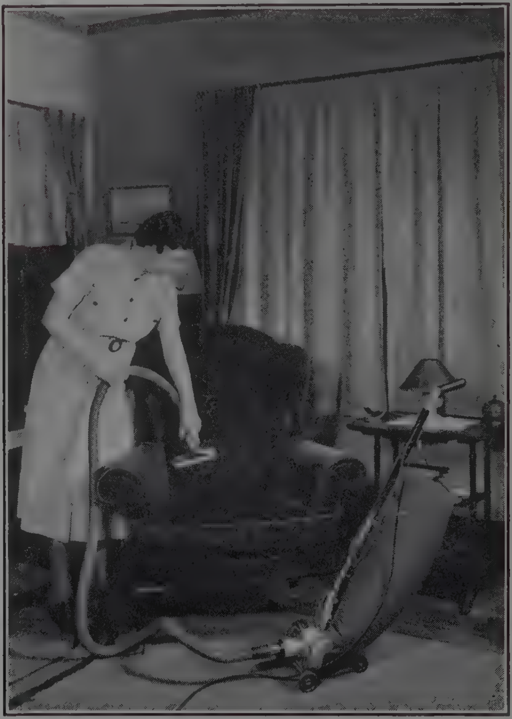

Figure 8. Household cleaning problems are simplified by the use of a vacuum cleaner at a power cost of one cent a month.

The vacuum cleaner is a real help to this farm homemaker, who resides near Muncie, in cleaning rugs. Attachments are used to clean the floors, walls, draperies, upholstered furniture and to spray paint.

Small Motor-Driven Appliances

The electric mixer is increasing in popularity in rural homes because of its variety of uses. It is used not only for mixing, beating and whipping, but may also be equipped with a variety of attachments for grinding, grating and slicing. Some farm homemakers use their mixers regularly for churn-

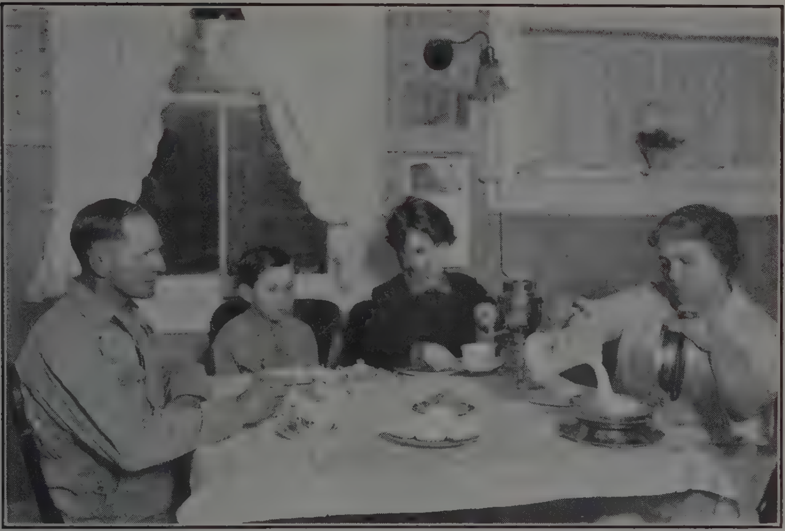

Figure 9. Electric cooking appliances make possible the preparation and serving of hot foods at the table as wanted.

The waffle iron and percolator in this Elkhart County farm home are used to prepare a favorite breakfast at a cost of less than five cents a meal spent for electricity.

ing, as seen in Figure 10. Mixers consume a very small amount of electric energy and will usually operate about ten hours on one kilowatt-hour.

Many women do a large part of the family sewing and find that an electrically driven sewing machine lightens the burden materially. A foot-power machine is tiresome to operate and reduces the amount of sewing which can be done in a given length of time when the operator provides the power. The majority of sewing machines may be purchased with motor drive but farm women have found the addition of a small motor to their foot-power machines entirely satisfactory. The sewing machine motor is so small its energy consumption will rarely exceed one kilowatt-hour of electricity per month even when a great deal of sewing is done.

The electric fan adds much to the comfort of the home on a hot day. It may be used in the kitchen while work is in progress there and is easily moved to other rooms when the kitchen tasks are finished. Household electric fans, as well as ventilating fans, can be used to force odors out of the kitchen and bring in fresh air. The electric energy used by a fan will depend upon its size but the common 8-inch fan is operated for 25 hours by one kilowatt-hour of electricity.

The electric clock, which requires no winding, oiling or regulating, is used in many homes and renders a valuable service as an accurate time keeper. The motor in the clock is so small that it uses only two to four watts and consumes from one to three kilowatt-hours per month. Some clocks are entirely automatic, that is, will continue operation despite a current interruption. A second type will start again as soon as the current is available but must be reset. A third type must be started and set by hand after any current interruption.

IVERSITY OF ARIZ LIBRARY

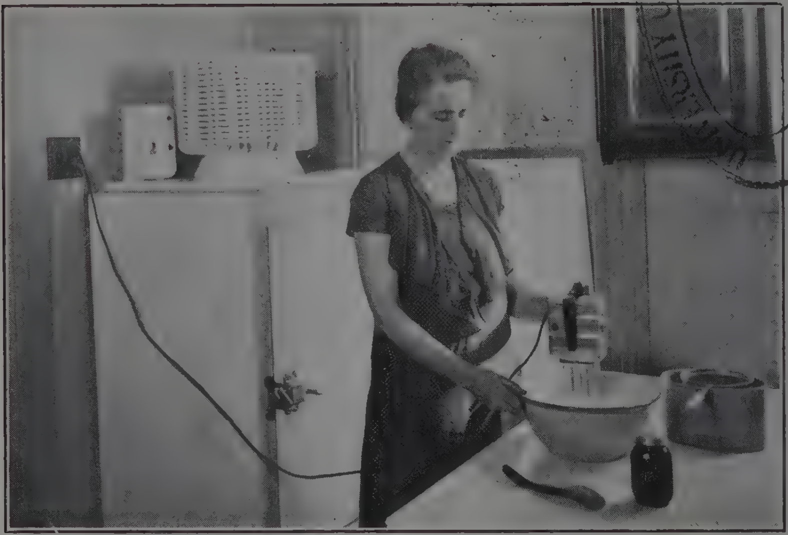

Figure 10. The electric mixer, with its attachments, performs many household tasks for less than one cent per hour power cost.

In addition to mixing, beating and whipping, the mixer on this farm near Matthews is used regularly for churning. Available attachments for some mixers include such equipment as fruit juice extractor, knife sharpener, food chopper and grater.

Table 1. Current Consumption of Household Equipment on Indiana Farms

Article	Consumption	Average
House lighting	10 - 20 kw.-hr. per month	
Water supply	2.1 kw.-hr. per month (house only)	
	6.2 kw. hr. per month (house and farm)	
Washing machine	0.5 - 4.0 kw.-hr. per month	2.3
Iron	1.7 - 6.3 kw.-hr. per month	4.6
Ironer	14.0 kw.-hr. per month	
Water heater	254.3 kw.-hr. per month	
Refrigerator	33.9 - 63.3 kw.-hr. per month	48.0
Range	53.0 -318.5 kw.-hr. per month	116.6
Sewing machine	less than 1.0 kw.-hr. per month	
Toaster	4 kw.-hr. per month	
Clock	1 - 3 kw.-hr. per month	
Vacuum cleaner	1.5 - 2.1 kw.-hr. per year	1.8 per year
Radio	1 kw.-hr. for 10-20 hours operation	
Waffle iron	0.1 kw.-hr. per person per meal	
Coffee maker	0.16 kw.-hr. per meal	
Mixer	1 kw.-hr. for 10 hours operation	
Fan, 8-inch	1 kw.-hr. for 25 hours operation

TWENTY-FIRST ANNUAL REPORT OF THE CREAMERY LICENSE DIVISION

T. H. BINNEY

Indiana Dairy Statistics

At the time of applying for the renewal of creamery licenses, all creameries, milk plants, cheese factories, condenseries, etc., report the amount of butter, milk, cheese, or other dairy products made or sold during the year. With this information, together with figures supplied through a co-operative agreement with the United States Department of Agriculture, Bureau of Agricultural Economics, it is possible to compile reliable statistics concerning the total production of licensed dairy manufacturing plants.

The following table is a summary of the reports received from licensed plants for the years indicated:

OUTPUT OF LICENSED PLANTS IN INDIANA FOR 1914, 1923, 1933 AND 1934

	1914	1923	1933	1934
Pounds of Butter	26,636,520	51,662,093	76,508,061	77,061,858
Pounds of Milk	51,067,066	213,578,850	463,359,717	486,921,912
Pounds of Cream	5,421,838	14,501,004	24,930,340	27,640,066
Gallons of Ice Cream	2,035,874	4,447,157	3,077,146	3,346,232
Pounds of Cheese	211,922	373,943	17,616,875	23,362,975
Pounds of Sweetened Condensed Milk	1,019,400	7,127,541	3,217,549	2,733,998
Pounds of Evaporated Milk	10,106,800	16,098,231	38,153,894	41,175,957
Pounds of Bulk Evaporated Milk	2,450,988	10,130,565	21,041,576	22,095,158

By comparing the figures for 1934 with those for 1933 in the above table, it will be noted that with the exception of sweetened condensed milk all products show an increase. The increase in the amount of butter made is 553,797 pounds, or 0.7 per cent. A total of 486,921,912 pounds of milk and 27,640,066 pounds of sweet cream were sold in licensed plants during the past year. This represents an increase of 5.0 per cent of milk and 10.8 per cent of cream in 1934 as compared with 1933. The amount of ice cream manufactured during the past year shows an increase of 269,086 gallons, or 8.7 per cent. Cheese production increased 5,746,100 pounds, or 32.6 per cent. Sweetened condensed milk decreased 483,551 pounds, or 17.6 per cent; evaporated milk (case goods) increased 3,022,063 pounds, or 7.9 per cent, and bulk evaporated milk increased 1,053,582 pounds, or 5.0 per cent.

In addition to the above products, dairy plants of the state manufactured 14,724,932 pounds of condensed skim milk; 778,157 pounds of evaporated skim milk; 151,372 pounds of concentrated skim milk (for animal feed); 6,484,139 pounds of condensed or evaporated buttermilk; 4,553,144 pounds of dried or powdered skim milk, and 1,633,831 pounds of dried or powdered buttermilk.

The following tables give the amount of milk which goes into the various dairy products handled in licensed plants and the distribution of milk in the state.

DISTRIBUTION OF MILK IN LICENSED PLANTS

Creamery Butter Used	1,618,299,018 pounds or	59.5%
Cheese Used	233,629,750 pounds or	8.6%
Ice Cream Used	46,010,690 pounds or	1.7%
Condensed and Evaporated Used	165,012,782 pounds or	6.1%
Cream Used	168,536,988 pounds or	6.2%
Milk Used	486,921,912 pounds or	17.9%
Total	2,718,411,140 pounds or	100.0%

Partial Distribution of Milk in Indiana

Handled in Licensed Plants	2,718,411,140 pounds
Shipped into State	189,886,824 pounds
Shipped out of State	258,412,696 pounds
Fed to Calves*	71,000,000 pounds
Retailed by Producers*	213,000,000 pounds
Used as Whole Milk on Farms*	411,000,000 pounds
Making Farm Butter*	158,000,000 pounds

*Milk Production Trends United States Department of Agriculture, June 10, 1935.

Station Operation and Equipment

In order to answer a number of questions which are frequently asked regarding cream stations in Indiana, a study of the operation and equipment of stations was made during the past year. The state was divided into nine sections as shown on the map on page 5. The data secured in the study is recorded in the following table. Of the 1,323 stations studied, 1,192 were company-owned stations and 131 were operated independently.

	Sec. 1	Sec. 2	Sec. 3	Sec. 4	Sec. 5	Sec. 6	Sec. 7	Sec. 8	Sec. 9	Total
Number of Cream Stations	111	129	115	102	144	160	240	145	177	1,323
Company owned stations:										
Indiana Creameries	90	115	91	73	112	91	207	50	54	883
Out of State Creameries	7	0	8	23	21	41	16	83	110	309

†Includes 3 Troemner Balances.
‡Includes 1 Troemner Balance.

Creamery Licenses

Every creamery, shipping station, milk factory, cheese factory, or person, agent, firm, company, association or corporation, receiving, buying and paying, for milk or cream on the basis of the amount of butterfat contained therein, shall be required to hold a creamery license. (Section 6, Chapter 340, Acts of 1913, Indiana.) The license is issued by the Purdue University Agricultural Experiment Station upon complying with the provisions of the Indiana Creamery and Testers' License Law. Such license is valid for a term of one year unless revoked by the Purdue University Agricultural Experiment Station.

During the past year 1,789 creamery licenses were issued. This is an increase of 33 over the previous year's total of 1,756. Plant licenses show a gain of 17 in number, while the number of station licenses show an increase of 16.

The following table is a summary of the kind of plants issued creamery licenses during the year ending March 31, 1935, and for previous years, as indicated.

Testers' Licenses and Examinations

To insure accurate tests to the producer and manufacturer, licensed testers are employed by all plants and stations where milk and cream are bought on a butterfat basis.

Before securing a license an operator must pass an examination which consists of both laboratory and written work. The laboratory work consists of testing samples of milk and cream in duplicate; the written work consists of answering twenty questions which pertain to the testing of milk and cream.

Five hundred and twelve candidates appeared for the testers' examination during the past year. This is an increase of ninety-one candidates over the previous year. Out of this number fifty-three failed to receive a passing grade; thirty of the failures were due to unsatisfactory written work, six were due to laboratory work and seventeen were due to both written and laboratory work.

Twenty hundred and seventy-five testers' licenses were issued during the past year, an increase of thirty-five over the previous year's total of twenty hundred and forty.

The following table shows the number of candidates examined and testers' licenses issued for the year indicated:

NUMBER OF CANDIDATES EXAMINED AND TESTERS' LICENSES ISSUED FOR THE YEARS ENDING MARCH 31, 1920, 1924, 1928, 1934 AND 1935.

	1920	1924	1928	1934	1935
Number of Individual Examinations	1,339	850	904	421	512
Number of Failures	226	125	290	24	53
Number of Persons Passing Examination	1,113	725	614	397	459
Number of Testers' Licenses Issued	2,371	2,518	2,661	2,040	2,075

The results of the forty-three examinations which were held at the seven examination points in the state are given in the following table:

RESULTS OF TESTERS' EXAMINATIONS 1934-1935

PLACE OF EXAMINATION	Number of Examinations	Number of Candidates	AVERAGE GRADES (PER CENT)		
			All Candidates	Candidates Passed	Candidates Failed
Lafayette	7	148	82.3	84.1	56.1
Muncie	6	75	81.1	83.4	62.5
Fort Wayne	6	69	83.7	85.1	62.2
Evansville	6	55	77.6	80.9	67.1
Terre Haute	6	38	80.9	83.5	59.2
Indianapolis	6	43	84.2	84.9	69.5
Seymour	6	84	79.9	83.0	61.0
Totals	43	512	81.4	83.6	62.5

Glassware Inspection

The Indiana Creamery and Testers' License Law requires that all milk and cream test bottles, milk pipettes, and nine-gram weights be examined for accuracy by the Purdue University Agricultural Experiment Station before being used in Indiana cream stations and dairy plants. All glassware conforming to the specifications given in Section 13 of the Law (Acts of 1913, Chapter 340) and found to be within the allowable tolerance are stamped with the letters "S. G. P." meaning "Standard Glassware, Purdue." The use of standard inspected glassware eliminates the possibility of incorrect tests from this source.

During the past fiscal year 45,380 pieces of Babcock testing glassware were examined by the Glassware Inspector of the Agricultural Experiment Station. In addition, 175 nine-gram weights were inspected and all found to be correct. This is 2,374 more pieces of glassware and 96 less nine-gram weights than were inspected last year.

The following table gives the amount of each kind of glassware inspected, and the number of pieces found to be incorrect:

KINDS OF GLASSWARE	Total Number of Pieces	Number Incorrect	Per Cent Incorrect
Cream Test Bottles	32,784	100	.305
Milk Test Bottles	9,888	5	.050
Milk Pipettes	2,708	0	.000
Summary	45,380	105	.231

Licenses Revoked

Inspectors of the Creamery License Division check the weights and tests made by operators of the Babcock test to determine their accuracy. If an operator is found to be testing incorrectly the inspector cautions him to be more careful in the sampling, weighing, and testing of milk and cream. Should later inspections show that incorrect testing is being done, whether intentionally or unintentionally, evidence is secured and presented to the State Creamery Examining Board at one of their regular meetings. At this meeting the operator is given an opportunity to explain the cause for differences between his tests and the tests made by the inspector. After careful consideration of the facts presented, the Board recommends to the Purdue University Agricultural Experiment Station the action to be taken.

During the past year the following testers were requested to appear before the Examining Board and, after considering the evidence, the Board recommended that their testers' licenses be revoked:

Miss Cordia King, Tell City, Perry County, Indiana, tester for Pure Cream Products Company, Tell City, Indiana.

Miss Edith Bender, Evansville, Vanderburg County, Indiana, tester for Sugar Creek Creamery Company, Evansville, Indiana.

Mrs. Flora Spence, Ridgeville, Randolph County, Indiana, tester for Sherman White & Company, Fort Wayne, Indiana.

Mr. Lawrence Abbott, Chrisney, Spencer County, Indiana, an independent buyer.

Mrs. Bess Meienberg, Brookville, Franklin County, Indiana, tester for Red 73 Creamery Company, Union City, Indiana.

Mrs. Velma Cavitt, Zanesville, Wells County, Indiana, tester for Zanesville Creamery Company, Zanesville, Indiana.

Mrs. Estella Dick, Alexandria, Madison County, Indiana, tester for Schlosser Bros. Creamery, Fort Wayne, Indiana.

Mr. William Griffin, Bloomington, Monroe County, Indiana, tester for Johnson Creamery Company, Bloomington, Indiana.

Mr. William Brougher, Grammer, Bartholomew County, Indiana, tester for Merchants Creamery Company, Cincinnati, Ohio.

ROSES

E. R. Honeywell,
Department of Horticulture

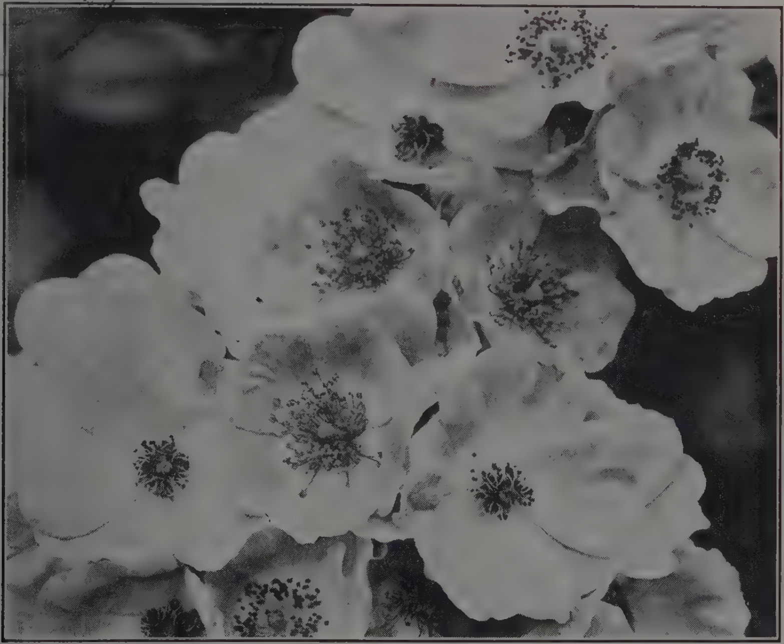

Figure 1. The Hugonis Rose (*Rosa hugonis*) is one of the best of all shrub roses.

The rose is considered the oldest of all cultivated flowers. Although very little is known of its origin, it is commonly referred to in the Bible, in Greek mythology, and in the writings of the ancient Roman philosophers and poets. It has played a definite part in wars and religious ceremonies, and has survived through the world's history. Today, more than ever before, the rose in its native and hybrid forms appeals more strongly for the part it has played.

This is evident by the fact that 11.21 per cent of all nursery sales, including both ornamentals and fruits, is for roses.* It is therefore easy to assume that the prestige of the rose is the same as it was nearly 2,600 years ago when Sappho proclaimed it the "Queen of Flowers" in the following words:

"Would Jove appoint some flower to reign
In matchless beauty on the plain,
The Rose (mankind will all agree),
The Rose, the Queen of Flowers should be.
The pride of plants, the grace of bowers;
The blush of meads, the eyes of flowers;
Its beauties charm the gods above;
Its fragrance is the breath of love;
Its foliage wantons in the air,
Luxuriant, like the flowing hair;
It shines in blooming splendor gay,
While zephyrs on its bosom play."

The purpose of this circular is to give a brief discussion of the essentials of rose culture, so that the rose may be more successfully grown.

CLASSIFICATION, USE, AND SUGGESTED VARIETIES

Roses vary greatly in plant habit, flowering characteristics, and use. For this reason, plants of similar characteristics are grouped into horticultural classes in order that one may have a better understanding of cultural principles.

The number of rose varieties available constitutes several thousand. An average of about 150 new varieties is described each year. Only a few of the best, well-known varieties representing each horticultural class are listed here.

Bush Roses for Landscape Effect

Indiana has long been known for its wild roses, which are commonly seen growing uncultivated along the roadside, on steep banks and fences, and in prairies and swampy areas. They often appear voluntarily where few other plants will thrive. Their ability to grow under so many different situations, their remarkable variation in height, and habit of growth, and their natural appearance make them ideal for naturalistic plantings, especially in parks and roadside plantings. The roses here suggested are of both native and foreign origin, including many hybrids which have proved satisfactory. Greater interest should be stimulated in the culture and use of such roses.

The Meadow Rose *(Rosa blanda)* is native to Indiana. The flowers are usually large, bright pink, and borne solitary, in pairs, or in clusters of three to five. Height 2-4 feet. Bloom in June.

The Bristly Rose *(Rosa nitida)* has been reported growing wild in Indiana. A very dwarf rose (1-2 feet) which is very useful in covering steep banks, or as a foundation planting for other roses. The flowers are usually solitary and bloom in June and July.

The Swamp Rose *(Rosa palustris)* is common throughout Indiana, growing in swampy areas. It is an upright shrub, often attaining 8 feet in height. The flowers are pink, about 2 inches across and bloom in June. A beautiful shrub when planted along the waterside. The bright colored hips (fruits) are attractive throughout the winter.

The Pasture Rose *(Rosa humilis)* is a very widely distributed rose generally attaining a height of 3-4 feet. The flowers are of medium size, usually solitary and bloom from June to August. It is useful for roadside planting.

The Austrian Brier Rose *(Rosa foetida)* is a large shrub, often 8 feet high. The flowers are bright yellow, 2-2½ inches across. There are several good hybrids. Two of the most common are: Austrian Copper and Persian Yellow.

---

*Data taken from "A survey of the Nursery Industry" by the American Association of Nurserymen.

The Sweetbrier Rose *(Rosa rubiginosa)* is a dense shrub which usually attains a height of 6 feet. The flowers are bright pink, about 1½-2 inches across. There are several good hybrids. Some of the best are: Jeannie Deans, Lady Pensance, and Rose Bradwardine.

The Scotch Rose *(Rosa spinosissima)* is a low growing shrub 3-4 feet with spreading branches. Flowers usually solitary and white.

The Rugosa Rose *(Rosa rugosa)* is one of the most popular of all shrubby roses, and is especially famous in winter for its attractive fruit. It is an upright shrub which attains a height of about 6 feet and is very hardy. Flowers red. Some of the best hybrids are: Alice Aldrick, Arnold, Agnes Emily Carman, Agnes, Belle Poitevine, Mme. George Bruant, Mrs. Anthony Waterer, and New Century.

The Hugonis Rose *(Rosa hugonis)* is one of the very best of all shrub roses. The foliage is refined, Acacia-like, and remains beautiful throughout the summer. The flowers are medium size and bright yellow. Height about 6 feet.

The Damash Rose *(Rosa damascena)* is a very hardy and robust grower about 5 feet in height. The flowers are generally borne in trusses of three or more, and are rather large, double, and fragrant. York and Lancaster is one of the best known hybrids.

The Cabbage or Provence Rose *(Rosa centifolia)* is upright in habit and attains a height of about 4 feet. It is one of the most fragrant of all roses. The flowers are pink and medium double. From this species a class of roses designated as *Moss Roses* has originated. They resemble the original rose in all characteristics, including fragrance, but in addition they have a mossy envelop which adorns the calyx. The flowers are very beautiful especially when in bud. Some of the best hybrids are: Anni Welter, Baron de Wassenaer, Celina, Comtesse de Murianais, and Venue.

The Wichurian Rose *(Rosa wichuraiana)* is commonly known as the Memorial Rose. It is a half-evergreen shrub with prostrate and creeping branches which make it the outstanding rose for covering steep banks, fences, and rockeries. The flowers are large and white. It is from this species that many of the best climbing roses have been developed.

The Prairie Rose *(Rosa setigera)* is a climbing native rose of Indiana which attains a height of 6 to 12 feet. The flowers are large, single, and deep rose-pink. It is a very hardy rose and should be used more freely for covering banks along roadsides and in general landscape plantings. (See back cover page.)

Bedding and Cutflower Roses

Roses of this group are grown primarily for their showy flowers of excellent size, fragrance, color, and quality. This is especially true of Teas, Hybrid Teas, and Hybrid Perpetuals. The flowers of the dwarf Polyanthas are borne in large clusters, are generally small, and have little fragrance.

Cold bleak winds of winter and dry hot winds of summer are the worst enemies of these roses. For this reason they should be grown in beds by themselves where they can be given adquate protection, free circulation of air, and the best growing conditions.

Teas.—These are generally supposed to be the progeny of the tea-scented rose *(Rosa odorata)* crossed with *(Rosa chinensis)*. They are characterized by their tea-like fragrance, their everblooming habit, long deep flowers, and their wide range of color. They are not considered frost hardy in Indiana unless given sufficient protection and the most of care. Suggested varieties are:

Alexander Hill Gray: pale lemon yellow and very double.
Bon Silene: soft rosy red shaded yellow, and semi-double.
Lady Hillington: deep saffron-yellow, slender pointed buds.
Marie Van Houtte: lemon-yellow, medium large and very double.
Mme. Antoine Mari: flesh-colored shading to lilac rose.
Mrs. Herbert Stevens: white, tinted pale lemon at center.

Hybrid Teas.—These are roses which have been mainly obtained by crossing varieties of Tea roses and Hybrid Perpetuals. They are noted for their fragrance, variety of color, size and character of bud, continuous flowering habit, and their ability to withstand garden conditions with moderate protection. They are well suited for bedding. Suggested varieties are:

Briarcliff: brilliant rose-pink, large pointed buds.
E. G. Hill: brilliant red, shading to darker crimson; very double.
Joanna Hill: creamy yellow, buds large and long.
Mme. Butterfly: light pink, tinted with gold.
Mrs. Aaron Ward: Golden buff, very attractive.
Premier Supreme: dark pink, very pleasing.
Red Radiance: deep rose-red, freely produced.
Souv. de Claudius Pernet: light-yellow, and very large.
Sunburst: yellow, strongly suffused with orange.
Talisman: scarlet-orange and rich yellow.

Hybrid Perpetuals. Roses of this class are often called Remontant. They are the result of many crosses between *(Rosa chinensis)*, *(Rosa centifolia)*, *(Rosa gallica)*, and *(Rosa damascena)*. They are characterized by their stiff, upright growth, wrinkled, dull green foliage, and large flowers which are inclined to be somewhat flat, and their hardiness. They flower in great profusion in June and early July, and if judiciously pruned back after flowering some additional flowers may be expected in mid-autumn. Suggested varieties are:

Anna de Diesbach: clear, rosy carmine, very large.
Frau Karl Druschki: snow-white flowers of beautiful shape.
General Jacqueminot: scarlet-crimson of moderate size.
George Arends: soft pink in various shades.
Mrs. John Laing: clear pink, very large, and smooth.
Paul Neyron: dark lilac-rose of immense size.
Ulrich Brunner: bright carmine-red.

Dwarf Polyantha or Baby Ramblers: Polyantha roses are hybrids of *(Rosa chinensis)*, *(Rosa multiflora)*, and various horticultural varieties. They form a class of everblooming roses with flowers produced in large clusters. They are small bushes seldom attaining more than 2 feet in height and are very hardy. Roses of this class are very well suited to Indiana conditions and should be grown more freely. Suggested varieties are:

Aennchen Muller: shining, bright pink.
Cecile Brunner: light pink with yellow base.
Eblouissant: glowing, dark red.
Golden Salmon Superior: bright, scarlet salmon.
Lafayette: bright red flowers in large clusters.
Miss Edith Cavell: brilliant scarlet-red.
Sparkler: brilliant red.
Triomphe Orleanais: bright cherry-red.

Climbers

Climbing roses are very effective when grown on arbors, pergolas, pillars, trellises, and for covering steep banks and fences. When in bloom they are very beautiful trained on porches, but when so used they should be given adequate supports and planted in such a manner that they will be exposed to full sunlight and a free circulation of air.

There are many classes of climbing roses, including climbing forms of Teas, Hybrid Teas, Hybrid Perpetuals, and others. As a group, the most satisfactory Climbing roses for Indiana are hybrids of *(Rosa multiflora)*, a vigorous climbing rose that produces many small flowers in large clusters and *(Rosa wichuraiana)*, a half-evergreen shrub with prostrate and creeping branches. Suggested climbers are:

(A)—Hybrids of *(Rosa multiflora)*
    Crimson Rambler: large clusters of crimson flowers.
    Dawson: small, double flowers of rose-pink.
    Goldfinch: large, creamy flowers with bright yellow centers.
    Ida Klemm: snowy white, borne profusely.
    Tausendschon: large flowers of many shades of yellow, creamy white, and bright rose.

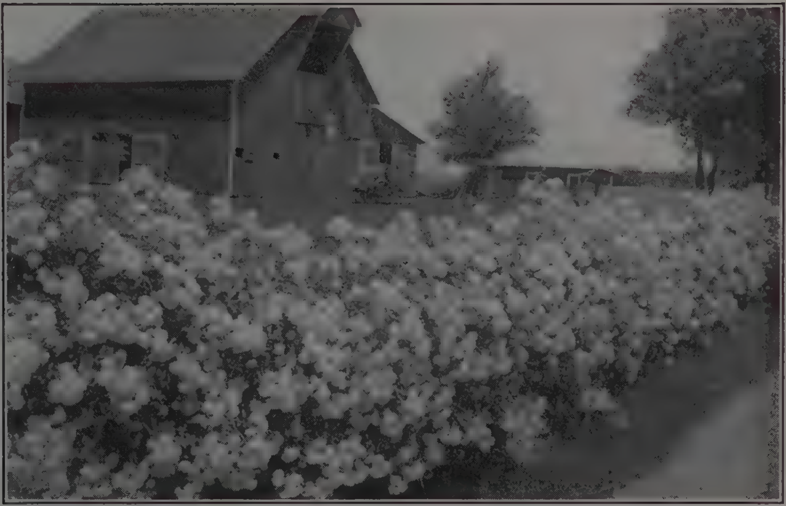

Figure 2. Climbing roses are desirable for screen plantings. Such a planting aids in concealing the barnyard and helps to break the wall surface of adjacent buildings. Roses prefer full sun exposure and a free circulation of air.

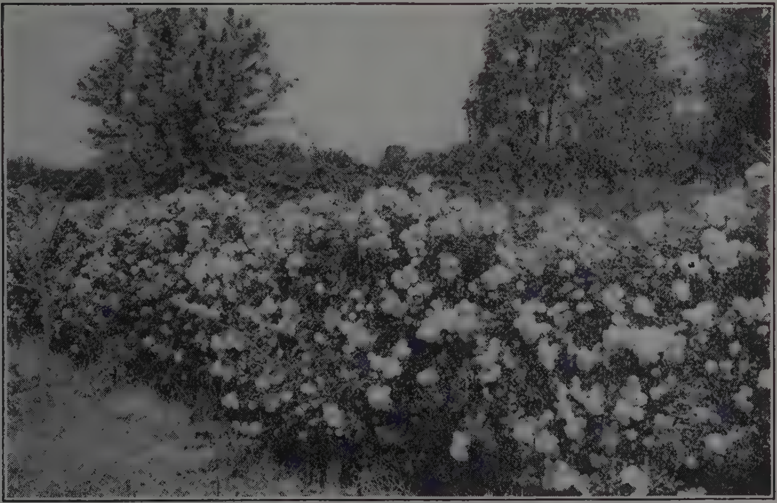

Figure 3. Highways can be made more attractive through proper selection, planting and care of climbing roses.

(B)—Hybrids of *(Rosa wichurainana)*

American Pillar: large, single flowers of crimson-pink.
Dorothy Perkins: miniature flowers of shell-pink.
Dr. Huey: large flowers of crimson-maroon.
Dr. W. Van Fleet: large pale pink flowers borne on long stems.
Excelsa: scarlet-crimson blooms with light streaks and shades.
Gardenia: yellow buds and ivory-white flowers somewhat deeper yellow in center.
Hiawatha: single flowers of brilliant carmine.
Mary Wallace: large flowers of bright pink.
Silver Moon: long, creamy white flowers with showy golden anthers.

PROPAGATION

It is obvious that the most economical way to replace or increase a selection of roses for the home garden is to purchase them directly from a local nurseryman. Nevertheless, there are occasions when in order to preserve certain memories, involving the rose, the growing of plants from successful propagation may be, and often is, the most fascinating activity in rose culture. Although plants may be propagated by several methods, those which may be employed most successfully are softwood cuttings, hardwood cuttings, division, and layering.

Softwood Cuttings.—Cuttings are sometimes referred to as "slips." Material used for propagation should be selected from vigorous, healthy plants. Flowering wood of the current year's growth is best suited. The cuttings should be removed from the parent plant with a sharp knife and should be at least three nodes (joints) long. The cut at the base of the cutting should be as straight across as possible, and just below a node. The leaves at the two lower nodes should be removed in order to prevent excessive loss of moisture from the cutting.

As soon as the cuttings are made thev should be placed in some convenient container, such as a flower pot or plant box, or placed in a cold frame or in

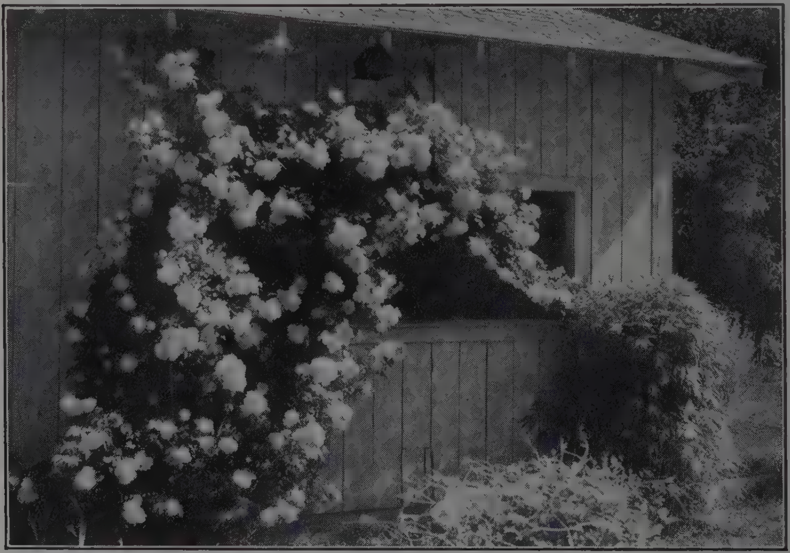

Figure 4. Climbing roses may make an uninteresting wall an attractive part of a garden enclosure.

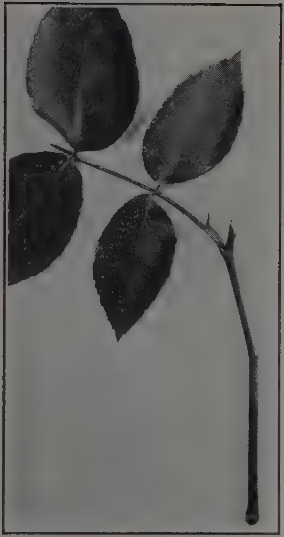

Figure 5. Softwood cutting.

some well protected place in the garden. They should then be thoroughly watered and shaded to prevent wilting. Sand or sand with the addition of leaf mold is the best soil media. The practice of placing inverted Mason jars over newly made cuttings to retain moisture and heat gives good results. As soon as the cuttings are well rooted the protection should be removed gradually in order that the plants may become accustomed to more adverse conditions.

Hardwood Cuttings.—Many kinds of roses can be successfully propagated by hardwood cuttings. This is especially true of large bush roses, Hybrid Perpetuals, and Climbers. The best time for making such cuttings is in autumn or early winter, preferably as soon as possible after the leaves have dropped. Only firm wood of the last season's growth should be used. The cutting should be made approximately six inches in length. The cut at the base of each cutting should be just below a node.

As soon as the cuttings are made they should be tied in bunches, keeping all the base ends on the same plane. Each variety should be properly labeled. The cuttings should then be placed in a box of moist sand, leaf mold, or sawdust and stored in a cool, damp cellar or basement. By early spring the cuttings should be well rooted, or at least well calloused, and should be planted out. They should be planted to a depth so that only the uppermost (terminal) bud is above the soil surface.

Division.—Many species of roses, such as those listed as being useful for landscape effect, may be successfully propagated from root shoots or suckers which are often freely produced. The best time of year for propagating roses in this manner is in early spring or fall.

Layering.—The propagation of roses by layering is a natural method by which many Climbers, Creepers, and Bush roses naturally increase. Branches which come in contact with moist soil develop roots, at the point of contact, and in time become individual plants.

Man can aid nature in this method by slightly notching the stems on the under side (preferably at a node) and bending them over to the ground and covering the injured portion with soil. This is best done in late spring and summer. By the same fall or following spring (all conditions being favorable) the buried portion will have developed roots and may be severed from the parent plant and be transplanted to another location.

Grafting.—Opinion differs so greatly as to the advantages of own roots versus grafted plants for ordinary garden conditions that it is very difficult to make a definite statement regarding their merits. As with all debatable questions, there is substantiated evidence for each. As observed by the writer, both own root and grafted roses (other conditions being satisfactory) will give good results under Indiana conditions. Certain varieties do seem to show greater vigor when grafted. Inasmuch as grafting involves tedious, long-time methods, it is obvious that such a method should not be attempted by the amateur. If grafted roses are desired, they are best obtained from those trained in the art.

WHERE AND HOW TO ORDER ROSES

Before placing an order for roses, it is well to study your needs and to know what varieties and types are best suited for your conditions. The best time to make a selection is when the plants are in bloom. Where possible, buy from your local nurseryman or from a nurseryman of long-established reputation. Try a few new varieties each year.

Generally speaking, field-grown plants are best for they are accustomed to outdoor conditions. Seldom do greenhouse-forced plants give satisfaction.

Place your order early for such orders can be given more individual attention. It is also important to state definitely when you wish your order filled and how it should be delivered.

The importance of securing good plants, properly labeled, packed, and delivered can not be over-emphasized. The small saving made by investment in cheap or inferior plants is usually lost many times over in lessened interest and pleasure in rose growing.

SOIL PREPARATION

Roses, as a group, vary considerably regarding soil preference. This is especially evident with wild roses. For example the Swamp Rose *(Rosa palustris)* is generally found growing in wet places, while the Pasture Rose *(Rosa humilis)* and the Meadow Rose *(Rosa blanda)* are generally found in dry sandy soils in prairie regions.

In general, however, it may be said that roses as a group respond best in soils which have been richly prepared and well drained. This is especially true of such roses as Teas, Hybrid Teas, and Hybrid Perpetuals. To prepare suitable conditions the soil should be well spaded to a depth of ten to twelve inches. If the soil seems heavy and poorly drained a three- or four-inch tile should be laid to provide sufficient drainage. A layer of gravel, cinders, or stones placed to a depth of ten or twelve inches may be used, but seldom gives as good results as tile.

Well-rotted manure, freely used and well incorporated into the soil is very beneficial. If manure is not available, well decayed, organic materials, such as leaves, lawn clippings, peat, or leaf mold may be used.

Commercial fertilizers may be safely used in soil preparation. Bone meal, or acid phosphate, applied at the rate of 10 pounds per 100 square feet of soil area is recommended. If such fertilizers are not on hand, a 2-12-4, 4-12-6, or one of similar analysis, applied at the rate of 4 pounds per 100 square feet of bed area is advised.

Lime is not a fertilizer and should seldom, if ever, be applied to garden roses, for most roses prefer soils which are slightly acid in reaction.

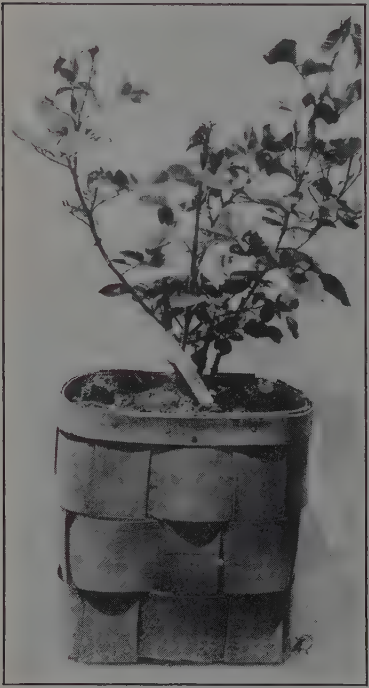

Figure 6. A field-grown plant which was dug while dormant in early spring and transferred to a plant basket for early sale. Plants so handled are planted with container intact and seldom show any ill effect of transplanting.

PLANTING

Time of year.—The proper time to plant roses is a very debatable question, for many factors must be considered. Climatic conditions, soil types, and kind of roses are important factors. As a general rule fall planting (October to November) is most favorable in Indiana. This is especially true with all roses except, perhaps, Teas and Hybrid Teas. Arguments in favor of fall planting are:

1. A more complete stock is available for selection.
2. More time and attention can be given to individual orders.
3. Plants are freshly dug; therefore, there is less damage due to storing and handling.
4. Weather conditions are usually more favorable.
5. More time for soil preparation.
6. Plants which become well established in the fall bloom more freely the first year.

If spring planting is practiced, it is important that the plants are set out as soon as the soil becomes workable. All dormant roses should be planted on or before April 15.

Care of plants on arrival.—As soon as the plants arrive they should be unpacked, inspected, and, if weather conditions are favorable, planted at once. If weather conditions are not favorable, the plants should be placed where they will neither freeze nor dry out. In case the roots have become very dry in transit, it is desirable to soak them in water a few hours previous to planting. If it is necessary that planting be delayed for several days, it is advisable to heel the plants in moist soil until time of planting.

Distance to plant.—Most roses are planted so closely together that adequate care can not be given. The following distances are suggested:

Large bush roses	4-6 feet
Teas and Hybrid Teas	1½ feet
Hybrid Perpetuals	2½ feet
Dwarf Polyanthas	2-2½ feet
Climbing roses	6-10 feet

Setting plants.—Planting consists of more than merely digging a hole, dropping a plant into it, covering its roots, and expecting it to grow. Each plant should be considered as an individual and so treated. The hole should be dug sufficiently deep and large enough that the plant may be placed and its roots spread out in a natural manner. Moist, mellow soil should then be worked in about the roots and well firmed to within about three inches of the soil level. The plant should then be well watered, which aids in firming the soil and driving out the air. As soon as all the water has settled, additional soil should be filled in about the plant. Each plant should be set at the same depth or perhaps one inch deeper than it originally grew in the nursery.

Pruning newly set plants.—All newly set plants should be pruned back in proportion to the reduced root system. This aids in stimulating stronger shoots and better quality flowers.

Pruning should consist first of cutting out all bruised and weak growth, and then cutting back the stronger canes. Most roses should be cut back so that only about one third of the original growth remains.

Protection.—All newly set plants, whether planted in spring or fall, should be provided with a mulch of well-rotted manure, straw, or peat, in order to preserve moisture and to prevent alternate freezing and thawing which results in soil heaving. See winter protection (page 11).

CULTIVATION AND FERTILIZATION

Roses require frequent, careful cultivation to keep weeds in check and the soil in the best physical condition. Deep cultivation is unnecessary and should be avoided as there is danger of disturbing the feeding roots.

A mulch of well-rotted manure or peat applied in early spring aids greatly in improving the physical condition, fertility, and waterholding capacity of the soil, and aids in modifying soil temperature to some extent.

The time to apply fertilizers to established roses is during early spring and through their flowering period. This enables the plants to make vigorous growth and flowers of good size and quality. Roses which are heavily fed in late summer and fall do not harden off properly and are subject to winter injury.

Chemical fertilizers are becoming more popular each year and should be used more freely by gardeners. A complete fertilizer, such as a 2-12-4, 4-12-6, or one of similar analysis, is recommended. Such a fertilizer, if used for roses, may be applied at the rate of two or three pounds per 100 square feet of bed area. Three applications should suffice: the first just as the plants are leafing out; the second just previous to flowering; and the third immediately after flowering. For large individual bushes or climbing roses, one-half cupful of a 2-12-4 or 4-12-6 fertilizer for each application should be adequate. Small plants should be given less in proportion to their size. Where possible, applications of fertilizers should be well incorporated into the surface soil previous to a rain. If this is not possible, it should be well watered in. Fertilizers should not be applied during hot dry weather.

WATERING

Roses require considerable water; this is especially true just previous to and during their flowering season. When the plants show need of water, water thoroughly. Frequent light waterings should be avoided for such a practice causes shallow root formation and makes conditions more favorable for diseases, such as black spot and mildew. Under ordinary conditions, evening or night waterings promote the best growth. Under no conditions is it advisable to wet the foliage and flowers during the heat of the day in full sunlight. Watering under such conditions results in scalding and promotes a weak, soft growth and flowers of inferior substance and quality.

WINTER INJURY

Winter injury to roses is a common cause of much discouragement in rose culture, much of which can be avoided if proper cultural conditions are practiced. There are two types of injury: (1) loss of moisture from the canes and roots by evaporation and (2) the actual freezing of the canes and roots.

Plants, although dormant, require moisture for evaporation continues throughout the plant at all times. In order that the twigs may continue to give off moisture the roots must remain active. Frequently high winds accompany low temperatures, and if the soil is not well protected it will dry out so rapidly that the roots will become severely injured. This in turn will cause the twigs and buds to dry out, shrivel and die for lack of moisture.

The actual freezing of plants is the result of ice crystals being formed within the plant tissue from water that has been withdrawn from the cells. Twigs which have been so affected present a brown, water-soaked appearance shortly after they thaw and are permanently injured.

In order to reduce winter injury to the minimum, early maturity is the most important single factor. While seasons vary greatly from year to year, certain cultural practices should be followed in bringing about as great a degree of maturity as possible. The following suggestions are offered:

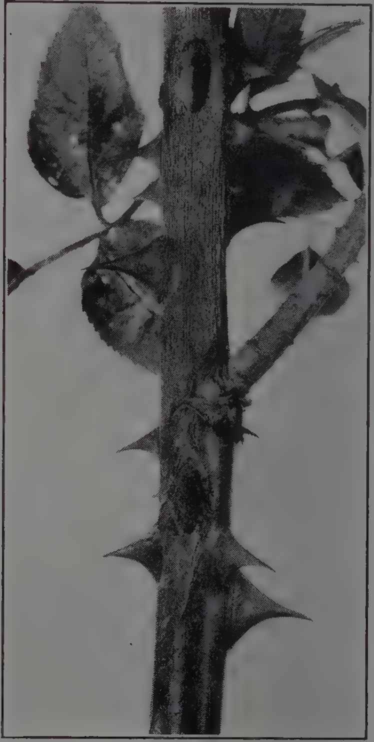

Figure 7. Winter injury. Early maturity of plants through cultural practices is the most important means of control. Winter protection is also beneficial.

1. Select those varieties that are known to be relatively hardy for your locality.
2. Roses which have become heavily defoliated during their growing season due to insect injury, diseases, or for any other reason, are more susceptible to winter injury.
3. Soils that are heavy and inclined to be wet delay maturity. Roses require adequate drainage.
4. Winter winds of high velocity may cause heavy injury. This is particularly true of roses which are grown in the protection of deciduous trees during the summer. Such trees afford but little protection during winter.
5. Cultivation and applications of nitrogenous fertilizers should be discontinued after August 1 in order that the new growth may have adequate time to mature before freezing weather.
6. Late summer pruning should be avoided, as it often stimulates new growth, which will not become sufficiently mature before winter.

WINTER PROTECTION

It is generally assumed that protection is applied to keep plants warm. This conception is not true. The real purpose is to keep the soil and plant temperatures as uniform as possible when the ground is once frozen, thus preventing alternate freezing and thawing which accompany the weather changes. No protection should be applied until the plants have become defoliated and the soil is frozen or about to become frozen.

Inasmuch as roses vary greatly in hardiness the requirements of the various groups will be considered individually.

Bush Roses.—Such roses are very hardy and seldom if ever need protection after once established. Mounding soil up about the plants in late fall for the first two years is suggested.

Teas.—Roses of this group are not hardy in Indiana, but, if grown, may be treated as annuals and replaced each year. Some growers treat them similarly to cannas, digging them each fall and storing them in cellars or basements and covering them with moist soil, then planting the following spring.

Hybrid Teas.—Hybrid Teas may be successfully carried over winter if adequate protection is given. The most common practice is to hill soil up about the plants to a height of about ten inches, and over the soil place a mulch of coarse straw or well-rotted strawy manure.

The placing of inverted fruit hampers or wooden boxes over the plants and hilling soil about them has given good results, but is rather unsightly.

Hybrid Perpetuals and Dwarf Polyanthas.—Roses of these two groups are comparatively hardy, but respond very favorably to protection. This is best provided by banking soil up about the plants to a height of eight to ten inches. Straw, leaves, or well-rotted strawy manure may then be applied as a mulch with good results.

Climbers.—Under ordinary conditions the Climbing roses mentioned (page 4) are comparatively hardy, although some winter injury is common each year. There are several methods of protecting such plants. Some of the most common are: (1) bringing all the canes together and wrapping with straw. Although this method is very effective, it is somewhat unsightly; (2) removing the plant from the trellis or support and laying it down and then covering it with soil. After the soil is well frozen add a layer of leaves or straw; (3) covering the entire plant with burlap while still intact to its support.

PRUNING ESTABLISHED PLANTS

Pruning is probably the least understood and the most neglected phase of rose culture. It may be considered an annual chore which, if properly done, will show definite response and pay adequate reward.

The purpose of pruning is to remove all dead and diseased wood, weak growth and interfering canes, to encourage new growth, increase size and quality of flowers, and to make the plants more shapely. The method and time of year to prune roses should depend on their flowering habit, the purpose for which they are grown, and, to some degree, upon varieties. Each plant must be considered as an individual and so treated if best results are to be secured. A good pair of pruning shears should be used. A knife is seldom satisfactory. The following suggestions are offered:

Bush Roses.—Roses of this group require only such pruning as the removal of weakened, dead, and interfering canes. Occasionally a few of the larger canes should be removed or shortened to prevent crowding. It is best done in early spring.

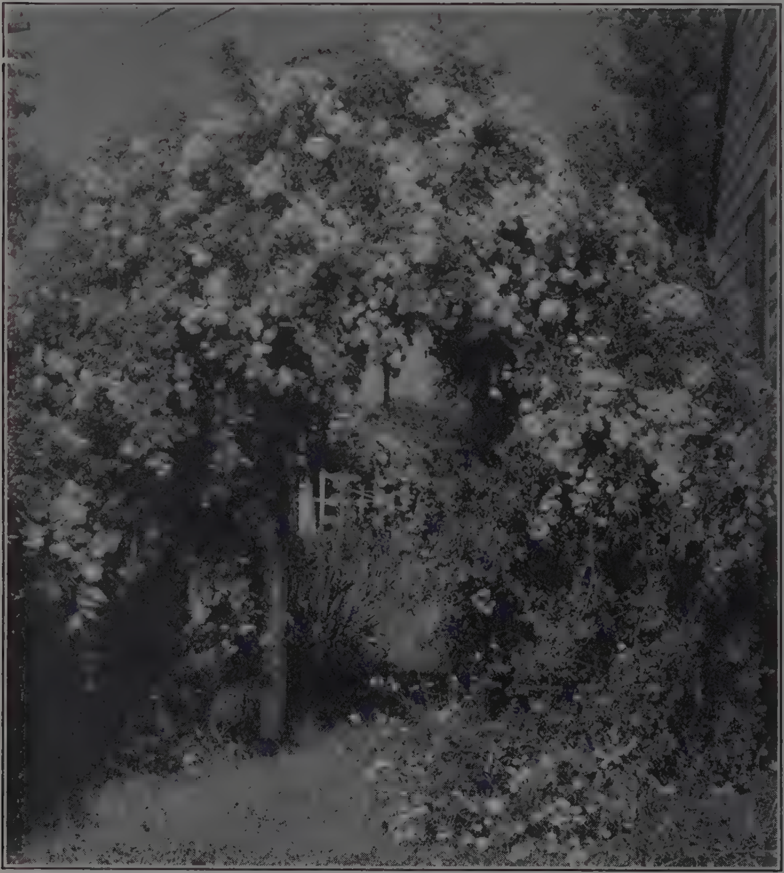

Figure 8. Neglected pruning. Climbing roses should be pruned annually as soon as possible after their flowering season. Most of the canes of the previous season's growth should be removed.

Tea Roses.—Tea Roses generally winter-kill severely each winter. All dead wood should be removed in early spring.

Hybrid Teas.—Roses of this group should be pruned severely, shortening each cane to about six inches in early spring. Heavy pruning stimulates heavier and stronger canes resulting in flowers of larger size and better quality.

Hybrid Perpetuals.—This group of roses should be less severely pruned than the Hybrid Teas for they produce their flowers upon the last season's growth. If judiciously pruned after flowering (July 1) they will often bloom again in mid-autumn.

Dwarf Polyanthas.—These roses generally flower throughout the summer. All old canes should be removed and canes of the last season's growth cut back about one-third in early spring. They flower on the current season's wood.

Climbers.—Roses of this group, including such varieties as Crimson Rambler, Tausendschon and Dorothy Perkins, should be pruned just after their flowering season. This is because they differ in their flowering habit from most other roses in that the next year's blooms are formed on the canes which were produced the previous year. Most of the old wood (one year or older) should be removed and the new (current year's) wood permitted to mature for next year's flowering. Such varieties as Dr. W. Van Fleet, Mary Wallace, Silver Moon, and Paul's Scarlet Climber should not be so severely pruned.

INSECTS AND ALLIED PETSTS*

Rose slugs.—Slugs are perhaps the commonest of outdoor rose pests and their injury is conspicuous because they skeletonize the foliage, causing the leaves to turn brown and drop or they may eat the entire leaf, depending on the species. Although there are three kinds of rose slugs, by far the most abundant is the one which feeds on the upper surface of the foliage and skeletonizes the leaves, leaving only a network of veins.

Control is easily obtained by spraying with lead arsenate, nine level teaspoonfuls to a gallon of water, or dusting with this poison or with calcium arsenate which has been diluted with four or five parts hydrated lime. Nicotine sulphate, diluted as for plant lice will also give good control if thoroughly applied.

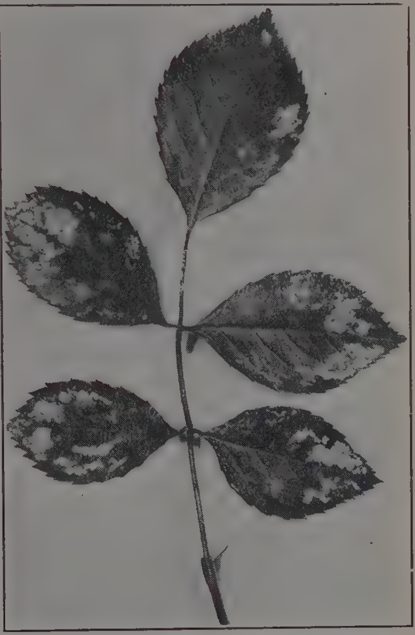

Figure 9. Rose slug injury. Leaves are skeletonized, turn brown, and fall prematurely.

Grasshoppers.—These insects are occasionally common and destructive to the foliage and flowers. If the plants are sprayed or dusted as for the slugs, this is usually ample protection. In severe cases poison bran bait may be used. This is prepared by mixing one teaspoonful of Paris Green with two quarts of bran. In another container dilute one-half teacupful of a strong grade of molasses with three teacupfuls of water. Then mix the diluted molasses with the poisoned bran and sprinkle the bait wherever the grasshoppers occur.

Rose chafer or beetle.—The rose chafer is a small robust, long-legged, clay-colored bettle which is especially fond of the buds and flowers of roses. They usually occur only in areas of sandy soil. Although they have chewing mouth parts. the usual stomach poisons are of little value. Perhaps best control can be obtained by dusting when the plants are dry with barium fluosilicate diluted with equal parts of flour.

---

*Prepared in co-operation with the Department of Entomology.

Leaf-cutter bees.—One frequently finds neatly cut circular areas cut out of the rose leaves, with no evidence of the culprit. These bees do not eat the foliage but cut the circular pieces to use in lining their nest, usually in pithy stems of plants. They do very little actual damage and no control is known.

Aphids or plant lice.—Aphids are the commonest of the several sucking insects attacking rose. The common species is about the size of a pin head, leaf-green in color, and they are usually found clustered on the developing buds or tender terminal shoots. These insects reproduce very rapidly and it is, therefore, highly important that control be attempted when the first individuals appear.

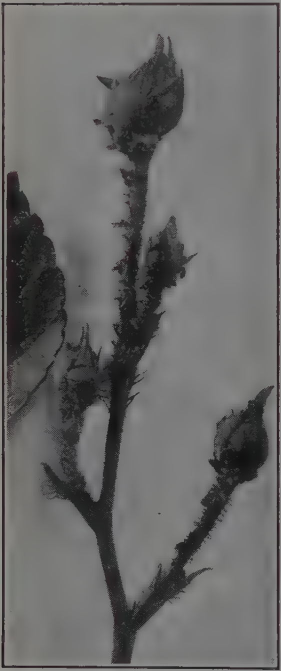

Figure 10. Aphids or plant lice on rose buds. These are sucking insects which generally feed on the terminal shoots causing a stunting growth and inferior flowers.

The material most commonly used to destroy aphids is 40 per cent nicotine sulphate, which is diluted at the rate of one and a fourth teaspoonfuls to a gallon of water in which a cubic inch of soap has been dissolved. Any of the other plant alkaloid materials, such as pyrethrum, derris, and rotenone, which are now commonly on the market, are effective. They should be used according to directions on the container. Whatever contact insecticide is used, it is important that it be applied as a fine, forceful spray and hit the insects to be destroyed.

Leafhoppers.—These are small green active insects which infest the under surfaces of the leaves. The immature individuals run quickly to the shaded side of the foliage when the leaf is turned over, while the adults fly when disturbed. Both immature and adult forms suck the juices of the plant. causing a whitening of the foliage, which results in premature dropping of foliage.

Any one of the contact sprays recommended for aphids is effective against the immature forms, but since the individual insects are quite active it is necessary to make a very thorough application. Excellent results will be obtained by dusting with equal parts pyrethrum powder and dusting sulphur and this combination will also check mildew as well as aphids, leafhoppers, and slugs.

Red spiders.—Tiny, speck-like mites usually infest the under surfaces of the leaves. These are known as red spiders and have sucking mouth parts and affect the foliage much as do leafhoppers. Dry conditions are favorable to red spiders and it is often possible to keep them under control by forceful syringing with water.

Sulphur is the specific remedy for these animals. Dry lime-sulphur, available at most dealers in insecticides, is used at the rate of one to two ounces per gallon of water, depending on the tenderness of the plants. Wettable, colloidal and liquid lime-sulphur is used as recommended on the container for plants in foliage. Dusting with a dusting grade of sulphur is also effective, but usually two or three applications are necessary.

Scale insects.—The San Jose and rose scales are the two most commonly attacking rose. They give the shoots a scurfy appearance. Heavily infested canes should be cut out and burned and the plants sprayed during the dormant season when the temperature is above 40 degrees Fahrenheit, using dormant strength lime-sulphur or spray oil, the latter being most efficient.

Rose stem girdler.—This pest is a native of Europe and has been reported from a number of regions in Indiana the past two years. It seems to attack by preference the rugosa types. This borer makes spiral burrows beneath the bark, causing a noticeable enlargement of the stem. The shoot eventually dies. Cutting out and burning infested shoots as they are observed is the only remedy.

DISEASES*

Black spot.—This is one of the most destructive diseases of garden roses. Practically all varieties are affected although some are fairly resistant, while others are extremely susceptible. The disease is characterized by large black circular spots on the upper surface of the leaf and surrounded by a yellow area. Under favorable conditions several spots may appear on a single leaflet involving most of the leaf's surface. The areas between the spots become yellow and the leaf falls prematurely. Under severe conditions plants may become completely defoliated.

One important step in the control of black spot is to destroy all infested leaves by burning. This is especially important in the fall because the fungus lives over winter on infected leaves. Dust the plants with dusting sulphur once a week during the growing season. Keep the plants growing vigorously by watering and fertilizing. Do not wet the foliage.

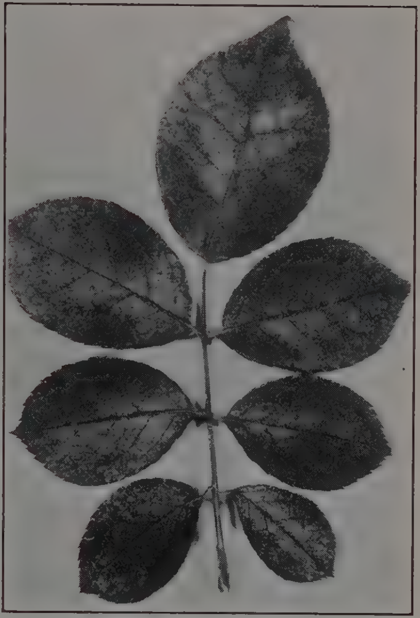

Figure 11. Red spider injury. These mites have sucking mouth parts and usually feed on the under surface of the leaves. The leaves become yellow and fall prematurely.

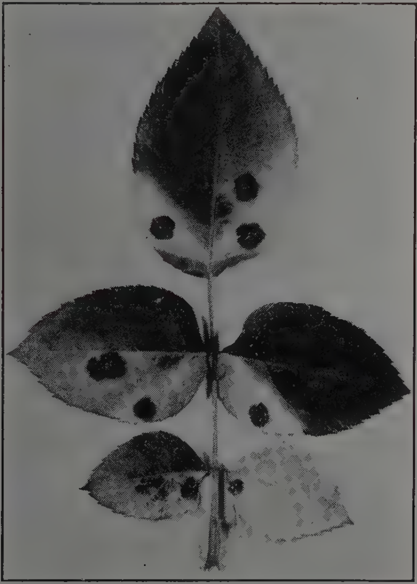

Figure 12. Black spot of roses.

Mildew.—This is an exceedingly troublesome disease which affects most garden roses, especially Climbers of the Crimson Rambler type. The first noticeable symptom is the formation of a white powdery growth on young leaves and buds. The mildew grows rapidly and may soon cover all buds, young leaves, and stems. In severe cases the leaves become dwarfed and distorted. The flowers open abnormally and wilt prematurely. Often plants are so badly infected that they become completely defoliated. The disease is most severe during damp cloudy weather but may be serious throughout the growing season.

This disease can best be controlled by dusting the plants at regular weekly intervals with dusting sulphur. The first application should be made as soon as the plants are well leafed out or as soon as the disease appears. Roses that are properly pruned and are exposed to free circulation of air and sunlight are less susceptible.

*Prepared in co-operation with the Department of Botany.

The Prairie Rose (*Rosa setigera*), a native of Indiana.

THE WAYSIDE ROSE

Out on the old highway it grows,
The wayside rose,
Rooted deep in the hard dry ground,
Swathed in the weeds that crowd it round,
Tended by naught but the rain and sun,
Its loveliness hidden, praised by none,
Contented, it blooms for the One who knows
Why it is there,—
This wayside rose.

Beaten by every wind that blows,
This wayside rose,
Asking not for a better place,
Where to unfold with ease and grace,
Wasting no time with excuses vain,
It brightens the weed-filled dusty lane,
An exquisite flower that blooms and grows
Perfect for Him,—
This wayside rose.

THE PURDUE PLOW TRASH SHIELD

R. H. Wileman
Department of Agricultural Engineering

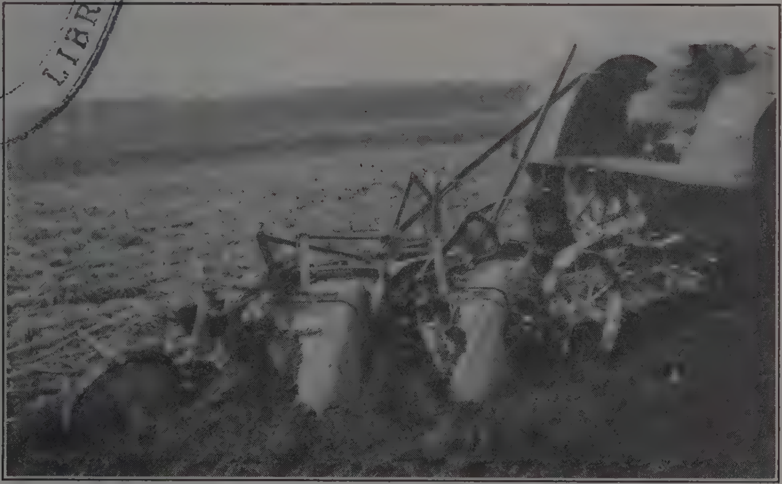

Figure 1. A 2-14 inch bottom plow equipped with Purdue Trash Shields turning under a heavy growth of corn stalks.

The need for some device or attachment for plows which would enable farmers to completely plow under corn stalks and other crop residues has long been recognized. The Purdue Plow Trash Shield is a result of European Corn Borer Control research conducted by the Department of Agricultural Engineering, Purdue University Agricultural Experiment Station. This shield makes possible clean plowing which is recognized as an effective method of controlling the corn borer. It eliminates the necessity for any treatment of corn stalks previous to plowing and the need for hand picking of trash after plowing to meet corn borer control requirements. The shield has also proven to be very effective for turning under sweet clover, soybeans, large weeds and similar materials. Clean plowing is generally recognized as a good farm practice and its value cannot be over emphasized. It materially aids in controlling weeds and eliminates much difficulty from trash clogging tillage implements and helps to control other insect pests as well as the European Corn Borer.

The Purdue Trash Shields can be adapted to and used on any wheeled plow. Their use is recommended on plows which are equipped with a good set of rolling coulters and jointers and have 14 inch or wider bottoms. They are not recommended unless good rolling coulters and jointers are used with them. Rolling coulters which are not less than 15 inches in diameter should be used. Coulters 18 inches in diameter are recommended. The large coulters mount trash much better, wear longer and give better satisfaction in every way.

These trash shields are constructed of sheet metal shaped to form a hood over the top side of the furrow slice as it is turned over. The rear edge of the shield is bent down so that it is perpendicular to the ground surface. This edge is irregular in shape and conforms to the contour of the turning furrow slice. The amount of contact between the shield and the soil is not sufficient to cause wear on the shield or add extra draft to the plow. The shield is hinged at the lower front corners and is free to rise and allow any obstruction to pass under it. This point of hinging is important as it allows the rear of the shield to rise without throwing the front portion out of its desired position. The shield is set so that its top is as near parallel to the turning furrow slice as possible and yet give a maximum amount of clearance for trash. This position of the shield with respect to the furrow slice prevents bunching of trash and bobbing of the shield.

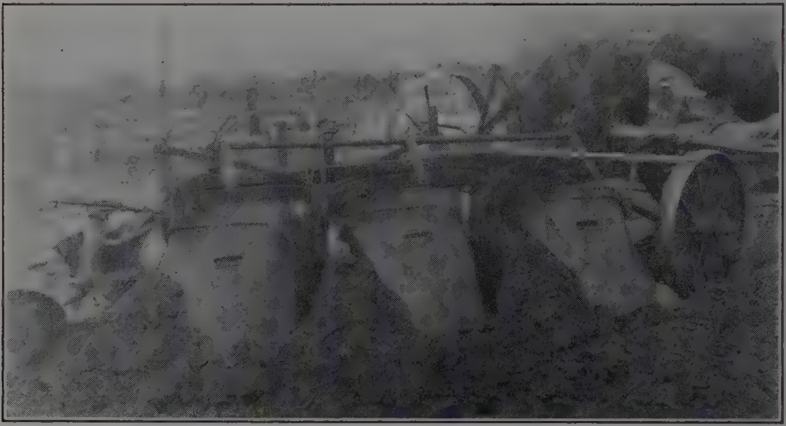

Figure 2. Close-up of trash shields in action.

The relation of the trash shields to the turning furrow slice, how they hood the trash and feed it into the bottom of the open furrow is shown in the above picture. Your attention is called to the sheet metal shield placed on the inside of the front furrow wheel. This shield prevents stalks and trash from catching in the spokes of the wheel and wrapping around the axle or being thrown onto the plowed ground.

The lower end of the shield extends over the open furrow and just clears the edge of the previously turned furrow slice. This edge of the shield is from four to four and one-half inches above the bottom of the open furrow. The portion of the furrow slice on which the stalks and trash are located is completely hooded. The trash to be buried is fed into the bottom of the open furrow immediately in front of the turning furrow slice. (See figure 2). The material being plowed under is buried deep enough so that little or no trouble is experienced from dragging it to the surface during subsequent tillage. When the plow is set to cut seven inches deep, numerous tests show that very little trash is found above four and one-half to five inches. Trash buried to this depth will not interfere with tillage operations. The trash is placed in the bottom of the furrow in the form of a roll which covers from one-third to one-half the width of the furrow. This leaves at least one-half the width of the furrow practically free of trash so that capillary action of soil water is not materially effected.

Good Rolling Coulters and Jointers Are Essential.—It is essential that the plow be equipped with a good set of rolling coulters and jointers to secure satisfactory results from these trash shields. The rolling coulter must cut through the trash and the jointer clean the edge of the furrow slice which when turned over lies against the previously turned furrow. The jointer throws this trash under the shield which feeds it into the bottom of the furrow where it is buried by the turning furrow slice.

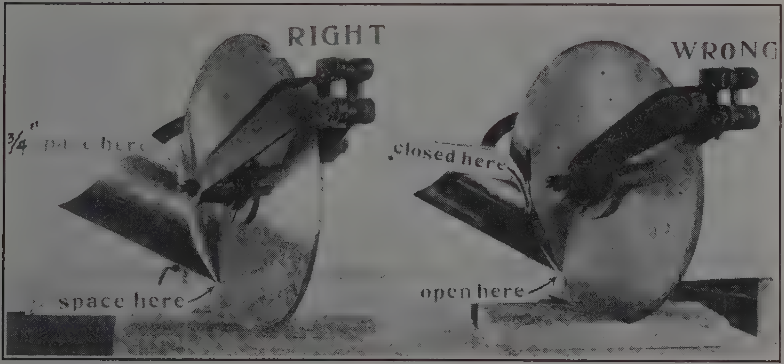

Figure 3. The right and wrong way to adjust a combination rolling coulter and jointer.

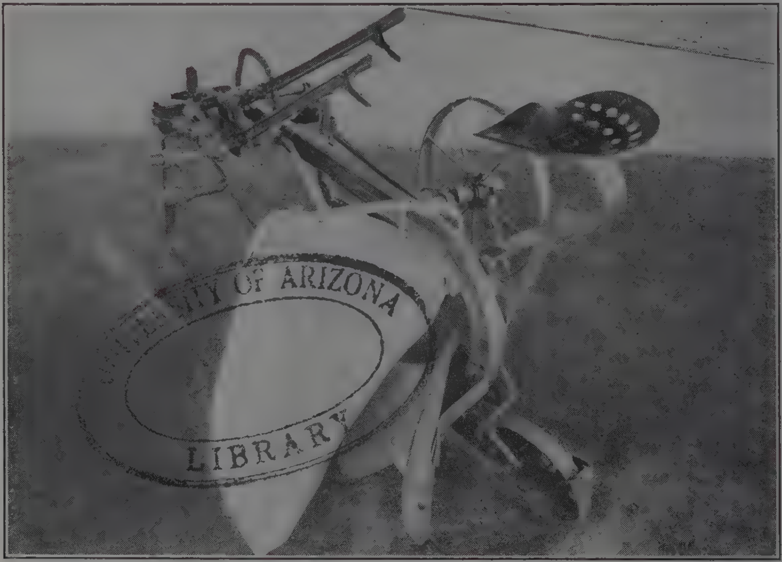
Proper Adjustment Prevents Clogging of Combination Rolling Coulters and Jointers.—This difficulty can be overcome in the following manner. The jointer should be adjusted with respect to the coulter so that the point sets from three-sixteenths to one-fourth inch away from the coulter when it is out of the ground. This clearance allows for the spring of the jointer arm caused by the pressure of the soil against the jointer when in operation and prevents the jointer from rubbing the coulter. The space between the jointer and coulter should gradually increase from the point upward as shown in figure 3. The distance between the top of the jointer and the coulter should be at least three-fourths of an inch. In order to obtain this adjustment it may be necessary to remove the bolts which hold the jointer point to the supporting arm and slot these holes slightly with a round file. This will allow more adjustment of the jointer point and make possible the setting described above. In some cases it may be necessary to straighten the edge of the jointer next to the coulter by grinding on an emery wheel.

When a plow equipped with trash shields is used to turn under corn stalks, large weeds, sweet clover and similar material, it is recommended that no treatment of the trash be made previous to plowing. However, when plowing with horses in heavy corn stalks, some previous treatment may be desirable to prevent the horses from dodging stalk rows and getting out of their proper position. In cases of this kind the following procedure is recommended. Cultipack or roll the stalks in lands the same as the field will be plowed. This should be done when the stalks are damp and tough so that they will not be broken loose from the ground or broken up more than necessary. A stalk which is fast to the ground is much easier to control than a loose one.



UNIVERSITY OF ARIZONA LIBRARY

Figure 4. A low lift horse sulky equipped with a Purdue Trash Shield.

Due to the variations in the construction of different plows, it is necessary to fit these shields to each make and type of plow. This is being done and at the present time blue prints have been prepared giving details for constructing these shields to fit 25 of the plows in most common use in Indiana. Others will be added as fast as time permits. These plans are available to anyone desiring them. There are several manufacturing concerns and blacksmiths in different sections of the state who have secured the blue prints and are in position to furnish these shields ready for installation on the plow. This enables anyone who is not equipped or does not care to make the shields himself to secure them already made. The cost has ranged from six to eight dollars a shield.

Anyone desiring trash shield blue prints or a list of concerns who can supply these shields ready to install on the plow can secure them from Purdue University Agricultural Experiment Station, Department of Agricultural Engineering, Lafayette, Indiana. A small charge is made for the blue prints to cover the cost of printing and mailing. When ordering trash shield blue prints be sure to give the following information. 1. Make of plow. 2. Number of the plow. 3. Size and number of bottoms.

Circular No. 218 April, 1936

The Wheat Meal Fermentation Time Test for Measuring Quality in Wheat

Fig. 1.—The cake maker and the bread maker require different kinds of flour and that means different kinds of wheat. The "fermentation time test" helps to classify wheats with respect to the kind of flour they will make.

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

The Wheat Meal Fermentation Test provides a rapid method of measuring the "quality" of wheat for different purposes. A given amount of whole wheat meal is mixed with a given amount of yeast suspension and made into a doughball. The doughball is then put into a beaker containing distilled water which is placed in an oven in which the temperature is favorable for yeast fermentation, gas evolution and disintegration of the dough mass. The length of time or "fermentation-time" required to start the breaking apart or disintegration process of the doughball is used as an index or measure of "quality" or gluten strength of flour which may be derived from a given sample of wheat. The result, or "fermentation-time", is recorded in minutes and is, therefore, the number of minutes that elapse between the time the doughball is placed in the distilled water and the time at which dough disintegration commences.

The method is simple and easily operated, though its very simplicity may easily become a pitfall to the operator who regards it as foolproof. Despite its simplicity of operation the wheat meal fermentation time test should be carried out with the same meticulous care as is accorded in making the protein test, the baking test, the viscosity test, or any other important laboratory test.

THE WHEAT MEAL FERMENTATION TIME TEST FOR MEASURING QUALITY IN WHEAT

By

G. H. CUTLER and W. W. WORZELLA

A suitable test for evaluating quality in small plant breeding samples has long been desired by breeders interested in developing new varieties of wheat of improved quality. The need for such a test has been rather keenly felt in recent years by breeders faced with the problem of combining suitable baking quality with other major characters, such as yield, cold resistance, disease resistance, etc. This undertaking has been somewhat complicated by the fact that it was necessary to go outside of our common wheats to species of wheats that are low and distinctly inferior in baking quality, in order to secure the desired disease resistance and winter-hardiness. Furthermore, in a breeding program large numbers of selections and recombinations become available and should be tested for quality especially during the early segregating generations when only a few grams of wheat are available. It was this type of problem that confronted the authors in carrying out a soft winter wheat breeding program in which an attempt was made to recombine in a wheat such characters as cold resistance, disease resistance, yield, and other essential economic characteristics in a wheat that would yield a flour suitable for pastry purposes. Careful consideration was given, therefore, to a test suitable for appraising the quality of small samples. The authors appreciate that the term "quality" though relative includes many factors. Of these probably the most important is gluten strength or baking strength as it is often referred to. It is in this sense only that the term "quality" is used in this paper.

In studying all phases of this question it was decided that a suitable test for evaluating quality must combine at least six major features, as follows: (1) the results obtained from such a test should be in agreement with the known baking quality and correlate with other important indices for quality, (2) it must be dependable and highly accurate, (3) it must be capable of testing as little as 2 to 5 grams of wheat (seed of an individual plant), (4) it must be quickly operated in order that all samples may be tested between harvest and seeding time, (5) it must be applicable, if possible, to wheat meal, rather than flour, since the latter requires too much wheat and, (6) its operation should be as simple as possible, consistent with a high degree of accuracy.

When gauged by one or more of the above requirements, it was surprising to find that all, or nearly all methods available were unsuitable. The one which seemed to possess the greatest promise was the little known and little used Saunder's Test. This method was investigated by the writers and it was found that wheat meal could be satisfactorily substituted for flour. Each step in the procedure was then studied and standardized. The method has been designated "The Wheat Meal Fermentation Time Test". It has been employed by the authors for some six years during which time more than 22,000 tests, mostly with soft and semi-hard winter wheats grown in Indiana, have been made with satisfactory results. Likewise, favorable results have been reported by some twenty Experiment Station workers throughout United States, Germany, Australia, Russia and Argentina, as well as by many millers. These investigators show that the results obtained with the Wheat Meal Fermentation Time Test, correlate with other indices of quality and are consistent and in agreement with the known quality of wheats as determined by the trade.

Standardizing the Procedure: Since the Saunder's Test was developed for the use of flour, it was necessary to check each step in the procedure in adapting it for the use of meal. Accordingly, the following were carefully investigated: (1) age of wheat, (2) preparation of the wheat sample, (3) moisture content of the wheat, (4) soundness, (5) plumpness or leanness of the wheat, (6) disinfectants, (7) meal fineness, (8) suitable grinder for reducing the wheat, (9) meal sampling, (10) size of sample and doughball, (11) size of beaker, (12) length of time required for kneading the doughball, (13) temperature of distilled water in beaker, (14) strength of yeast suspension, (15) consistency of doughball, (16) suitable oven for fermentation, (17) oven temperature, and finally, (18) the end-point of disintegration of the doughball for different types and classes of wheat. When each step was fully investigated and the resulting data carefully analyzed a method of procedure was formulated. Later, following further experimental testing, the method was standardized and designated The Wheat Meal Fermentation Time Test. It is outlined in full in this publication and is referred to both by its full name, and by the fermentation time test. It may not suit all classes and conditions of wheat, though it has not been found necessary to modify it even after six years use on soft and semi-hard winter wheats in which more than 22,000 samples have been tested.

The Method

Preparing the Wheat Samples:—Dry, sound, clean, normal wheat representative of the bulk of the sample from which it is taken is used. Scabby, dirty, weevilly, shrunken wheat or seed treated with disinfectants should not be tested as they do not respond satisfactorily. Wheat should not contain over 13 to 13.5 per cent of moisture; less than this amount gives better end results since it permits of more normal doughball formation and disintegration.

Age of Wheat When Tested:—Inasmuch as wheat continues to undergo changes in "quality" and condition for some time after harvesting, the authors follow the practice of testing for "quality" any time after six weeks following wheat harvest. Furthermore, samples whose "quality" is to be directly compared are tested within a relatively short period of time. It has been found too that the "quality" of ground wheat changed more rapidly than unground wheat and it varies to some extent with the variety of wheat. Grinding, therefore, is done the same day that the fermentation tests are carried out.

"Raw" Wheat is Ground into a Meal:—Wheat meal, not flour, is used when measuring gluten quality by the wheat meal fermentation time test. The wheat is ground to a proper fineness by means of the Labconco Mill (Fig. 2). This mill grinds rapidly, is easy to operate, cleans itself quickly and thoroughly and is readily adjusted so as to secure the desired fineness of meal. The adjustment is made at the rear end of the motor. This, when set at "F", gives meal of satisfactory fineness. Usually the practice is followed of turning the adjustment clockwise as far as it will go, then in the opposite direction until the pointer is opposite "F".

No doubt other suitable grinders may be found on the market. Grinding of the meal, however, is so vital to correct results that proper grinding cannot be overstressed.

Sampling the Meal:—The meal should be tested within a day after it is ground since meal allowed to stand will undergo changes that will modify its quality and also the "fermentation time." When ready to sample, carefully mix the wheat meal to insure an even distribution of the finer and coarser particles (Fig. 3), (Fig. 4).

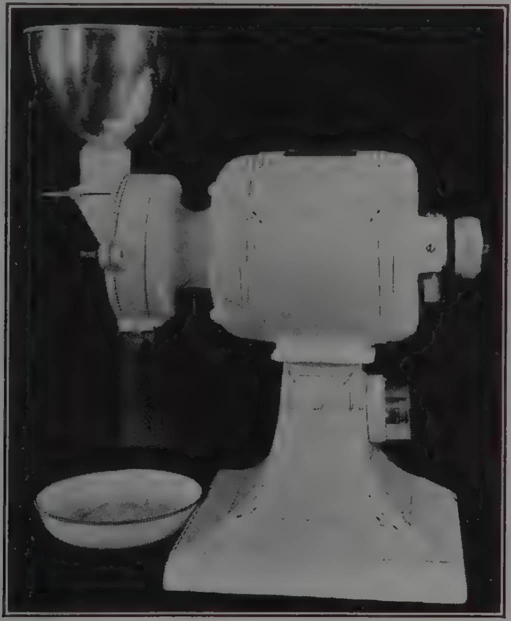


Fig. 2. The Labconco Mill

Making the Yeast Suspension:—Prepare a yeast suspension by dissolving 10 grams of Fleischmann's compressed yeast in 100 c.c. of distilled water. A new solution should be made up each day from fresh yeast, or from yeast kept in a refrigerator or ice box.

Making the Doughball:—Weigh out in triplicate 10-gram samples of meal and place into 150 c.c. beakers (as little as 3.5 grams of meal have been used with satisfaction by proportionately reducing the size of the beaker, the amount of yeast suspension and the amount of distilled water in the bath), and by means of a pipette add 5.5 c.c. of the yeast suspension (stir suspension for each doughball to insure uniform mixture) which is maintained at 80 degrees Fahrenheit (Fig. 5), and with a glass stirring rod mix into a coherent mass (Fig. 6). The mass is then transferred to the palm of the left hand, and with the thumb of the right hand is kneaded (for about a minute), until it becomes a doughball of *medium stiff consistency* (Fig. 7). Since the moisture absorption varies with different wheat varieties and strains, some doughballs may require additional water; hence moisture (do not add more of the yeast solution) is added when needed, followed by further kneading until the right consistency is obtained. Finally the ball is rolled in the hands into a small sphere, free from folds and crevices.

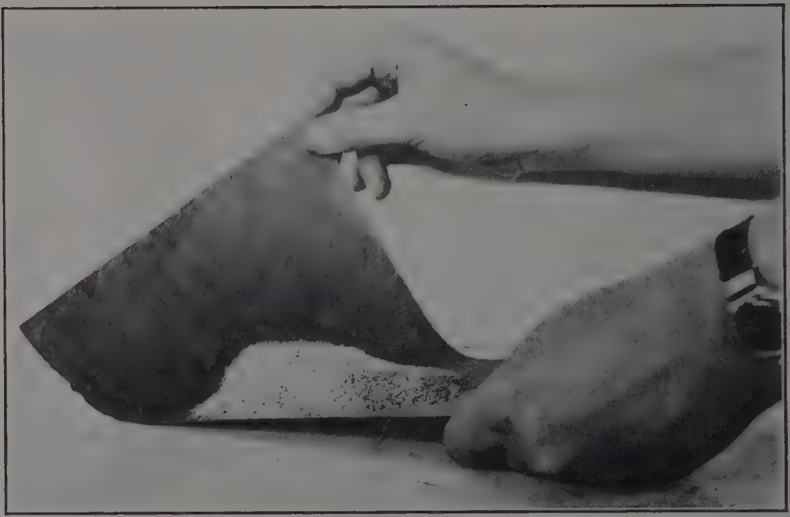

Fig. 3. Mixing the Meal

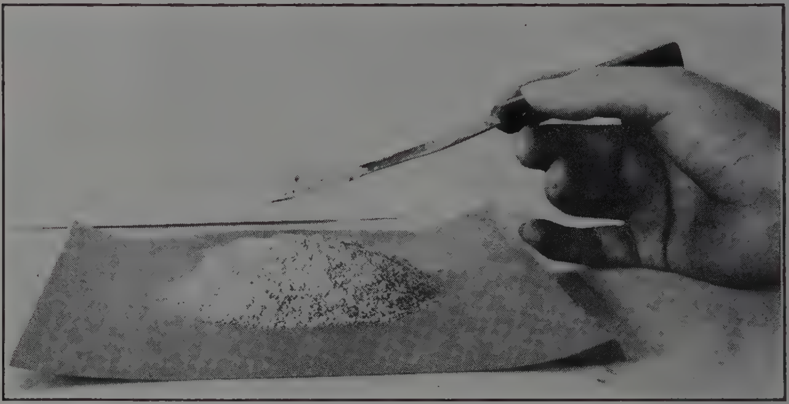

Fig. 4. Sampling the Meal

The Fermentation Test:—In making the fermentation tests, it is recommended that a standard wheat of known "time" be tested each day, or, better still, with each series of tests to serve as a check or control. Such a practice will be found helpful, especially in comparing results obtained on different days. Each 10-gram doughball is placed in a 150 c.c. low form beaker containing 80 c.c. of distilled water kept at 80 degrees Fahrenheit. The ball falls immediately to the bottom of the beaker. *The time of immersion of the doughball is at once recorded.* Place the beakers containing the doughballs in a fermentation cabinet equipped with transparent sides where a uniform temperature of 80 degrees Fahrenheit is maintained (Fig. 8). Regular observations are made on the behavior of each doughball.

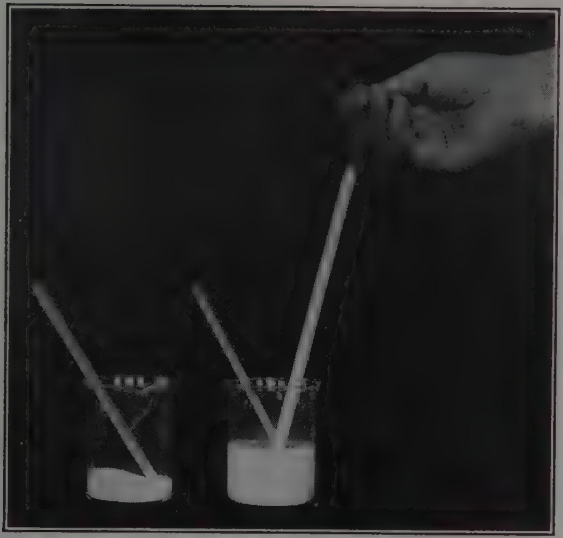

Fig. 5. Sampling the yeast suspension

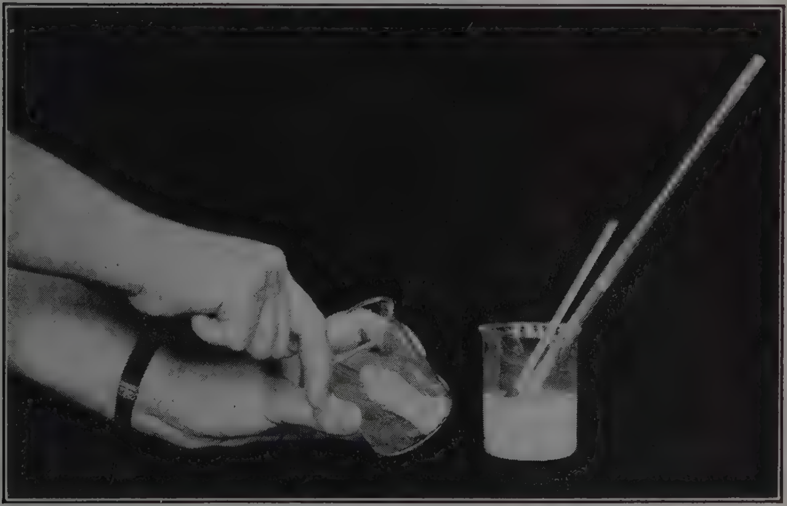

Fig. 6. Mixing yeast and meal into a coherent mass

As soon as fermentation gets under way, the ball becomes buoyant, rolls about and rises to the surface of the water. Soon it begins to swell and assumes a larger volume; in soft wheats this form may be more or less spherical (Fig. 9), while in the harder wheats it becomes flat and tends to cover the entire surface of the water (Fig. 10). The size and volume of the doughball gradually increases, and sooner or later, depending upon the gluten strength of the wheat being tested, gives evidence of breaking apart. *When the dough thus begins to detach itself and falls to the bottom of the beaker the time is again recorded.*

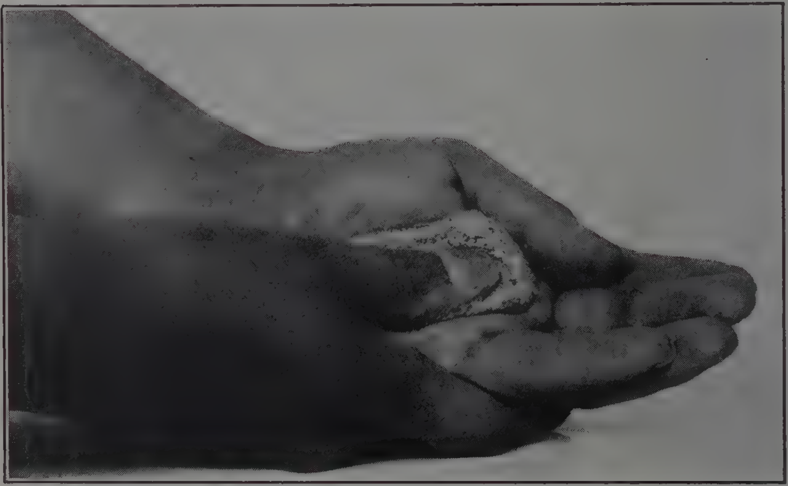

Fig. 7. Kneading into a doughball

Determining the End-point of Doughball Disintegration:—The end-point in doughball disintegration, or point at which the time is recorded, is a feature of this test which may prove a source of some difficulty, especially to operators who are unaccustomed to it. Here is certainly a place where experience will prove a good teacher because of the inevitable variation in the behavior of doughballs in the beaker. In the stronger gluten wheats the doughball tends to cover the surface of the water in a flat, fleecy-appearing mass—while the weaker gluten, soft wheats assume a spherical form and rarely fill up the beaker. Furthermore, the harder wheats with the tougher glutens require a distinctly longer interval of time before disintegration commences. Usually they start to tassel off on the under side of the ball, but sometimes a part of the side or edge of the doughball may break off and fall to the bottom, or the edges may curve under and the whole mass sink. At this point the time is recorded.

The soft wheat doughballs as a rule assume a more spherical outline. Those with medium strong glutens (40 to 125 min. wheats) disintegrate by pieces of different sizes breaking away; or the bottom part of the ball may all fall away. In others, the doughball becomes "water-logged" and sinks in a mass. On the other hand some doughballs from the weaker gluten wheats (the 15-30 min. white soft wheats) present quite a different type of disintegration. In these, minute dough particles begin to fall off in one or more places and this proceeds until in 1 to 3 minutes the particles become so numerous as to give the appearance of a "shower". Thus does the end-point or beginning of doughball disintegration manifest itself in different ways, in different wheats. In our experience, however, in the Department of Agronomy, where different operators are using the fermentation time test on wheats showing wide differences in doughball behavior, little or no difficulty is encountered in determining the end-point. With experience the operator of the fermentation time test soon gets to "know" his doughballs.

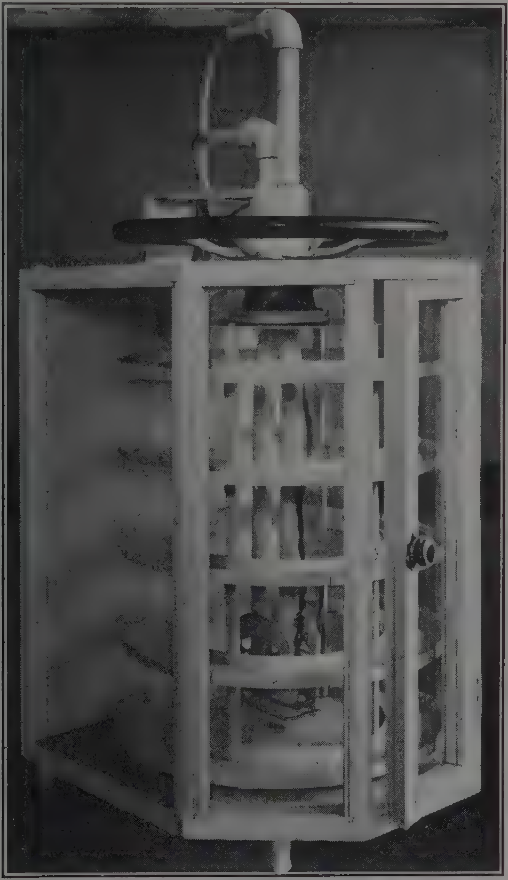

Fig. 8. Fermentation Cabinet suitable for testing "quality" of wheat by the wheatmeal fermentation time test. (Designed by the authors in 1932).

Measure of Gluten Quality:—The "time" or fermentation-time, as it is termed, for each sample is thus obtained. It is recorded in minutes, and is therefore the *number of minutes that elapse between the original immersion of the doughball and the beginning of disintegration of the doughball.* Hence the "fermentation-time" recorded in minutes becomes the index or measure of "quality". The longer the time the stronger the gluten quality; this may vary from as low as 15 minutes, in some of the soft wheats, to 400 or more in the best hard varieties. The wheats preferred for bread flours require a long "fermentation-time", while the ones preferred for pastry flours have a short "fermentation-time".

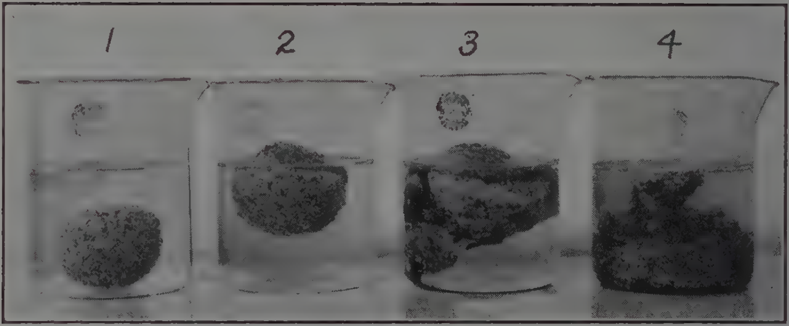

Fig. 9. Behavior of a doughball from a soft wheat. 1, doughball just immersed when time is first recorded. 2, doughball 20 to 30 minutes later. 3, the first piece of dough has just split off. At this stage the time is again recorded. 4, doughball 10 to 15 minutes later when it has disintegrated and completely fallen apart.

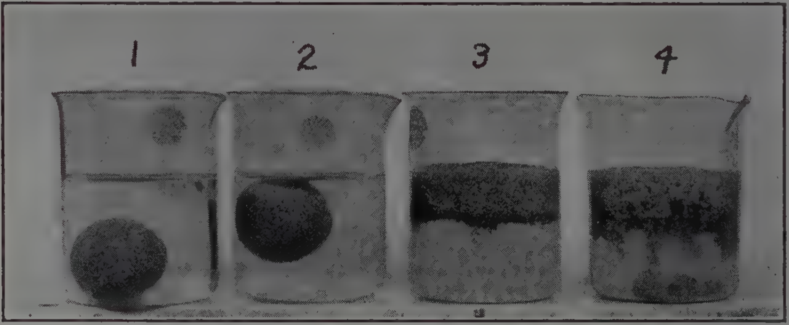

Fig. 10. Behavior of a doughball from hard spring wheat. 1, doughball just immersed when time is first recorded. 2, doughball 20-30 minutes later. 3, the first piece of dough has just detached itself and is still hanging like a small tassel to the under surface. At this stage the time is again recorded. 4, doughball three or four hours later in slow process of disintegration.

Variation in Fermentation-Time:—A 10 per cent variability rule has been adopted as a basis of agreement among triplicate doughball tests from the same lot of meal. When satisfactory agreement is not obtained, the entire test is repeated. No difficulty has been experienced in applying this rule to tests made on typical soft, semi-hard and hard varieties, when grown under their accustomed range of adaptability for quality, for their respective classes. It should be said that in our entire experience with the wheat meal fermentation time test it has seldom been found necessary to repeat a test.

Testing Millers' Samples:—In order to know the "quality" of wheat desired by the miller, one of the first steps in the soft winter wheat breeding program in the Agronomy Department at Purdue University Agricultural Experiment Station, was to obtain a large number of samples of wheat direct from the Indiana *millers*, just as they use it from day to day. These have been obtained more or less continuously over a period of years, and tested by the wheat meal fermentation time test, and the results thus secured are used as a guide in developing wheats suitable to meet miller and baker requirements.

Milling and Baking Tests Still Essential

As already emphasized a quick, dependable test for gluten quality will not only reduce time and expense in a wheat breeding program to a minimum, but, of utmost importance, new wheats of the desired "quality" can be readily developed to meet every commercial need. Of significance, too, is the fact that the miller's interests can be safeguarded since all plant selections can be tested during the early segregating generations when they may be rejected at little or no loss to the breeder should they fail to give promise of producing strains that will measure up to the specific requirements of miller and baker.

The Wheat Meal Fermentation Time Test measures a very important component of quality in wheat, namely, gluten strength. However, there are other components of quality, such as color, flour yield, fineness of flour, etc., which are not measured, and these must be determined by the milling and baking and other tests. When promising strains become fixed and a sufficient quantity of uniform grain is available, and certainly before a new variety is distributed to farmers for commercial production, milling and baking tests should be undertaken to obtain complete data on quality.

The Wheat Meal Fermentation Time Test and the Millers:—While the fermentation time test has been developed primarily for the use of wheat breeders and geneticists who have only small quantities of seed available, especially in the early segregating generations, and are therefore unable to use the baking test, it seems to offer much promise also as an aid to the miller and elevator operator. Perhaps even the cereal chemist may find use for such technic. Inasmuch as this test requires a minimum of time and seed, is simple and inexpensive to operate, it seems to lend itself peculiarly to the needs of the miller.

In discussing the fermentation time test recently before a group of millers, one of them remarked, "If this test evaluates 'quality' for the wheat breeder as accurately as experimental data would seem to indicate, will it not serve equally as well for those interested in the merchandising and processing of wheat?" In other words, why cannot the miller and others interested utilize such a simple test to advantage to himself and the milling industry? In response to such an inquiry, it may be stated that already there are numerous millers in Indiana, Ohio, and Michigan who are using this test with satisfaction.

There seems to be much promise that the fermentation time test will render an important service to the milling industry. Several hundred cooperative tests made for different Indiana millers during the past five years amply bear out this statement. Furthermore, because of the small amount of seed required, ease, simplicity and quickness in making the test, large numbers of small samples of wheat can be tested in a short time to determine their fitness for specific purposes, at low cost. Accordingly, small farm-samples representing different varieties or classes of wheat, grown in different seasons, and on different soils both high and low in fertility, in different sections of the country, can be tested quickly as to their suitability for a given purpose. Furthermore, market samples can be forwarded long distances if necessary by mail in small quantities and tested in the same way.

Some millers are now using the fermentation time test as an aid in buying and binning wheat for their regular milling operations. They find it capable of furnishing valuable information especially when used in conjunction with the protein content, viscometer data, etc.

A Classification of Wheats Based on Utility and "Quality" is Suggested:— Studies of "quality" with the aid of the fermentation time test on a wide range of wheats including classes, varieties, strains, and commercial samples, have served to emphasize the possibility of classfying wheats on a utility basis when fermentation time is made the measure of "quality". Accordingly, two general groups of wheat might be set up, viz: Soft or pastry wheats and hard or bread wheats, respectively (the durum wheats are not considered in this classification). These, in turn, can each be further subdivided into four or more classes or fermentation-time groups in keeping with gluten strength and uses or purposes to which such wheats are put, as follows:

I. Soft or Pastry Wheats

Classes	*Fermentation-Time Groups*
Very weak	Less than 30 minutes
Weak	30- 50 minutes
Medium strong	50-100 minutes
Strong	100-175 minutes

II. Hard or Bread Wheats

Weak	150-225 minutes
Medium strong	225-300 minutes
Strong	300-400 minutes
Very strong	400 and over

The authors fully appreciate the difficulties involved in a proposal to set up ironclad groups by which wheats may be classified on the basis of utility and "quality". Obviously, there must of necessity be flexibility to such a classification in order to allow for variations in the behavior of wheats due to soil and climate influences, not to mention the requirements and methods of the miller. The fact too that there is an overlapping between the soft and hard wheats, where the strong of the soft and the weak of the hard are similar in milling and baking qualities and may not infrequently be used for the same purpose, seems to add to the difficulties. Notwithstanding all of these variations, with utility and "quality" as the basis, it seems to matter little how the "quality" varies so long as the different manifestations can be correlated with utility. The value of such a scheme of classification lies in the fact that the users of wheat, whether interested in the manufacture of flour for cakes and bread of the different types, for biscuits, pastry, crackers, or flour for family uses, are enabled to find common ground on which to stand with the wheat breeder and producer. The authors offer such a classification for purposes of inviting discussion rather than as a perfected working model.

Blending Wheats:—The fermentation test offers much promise as a tool in the blending of wheats. Experimental data based on large numbers of blends and shown graphically in Fig. 11, suggest that the miller may also expect some valuable assistance in this respect from this test.

The results (Fig. 11) show quite conclusively that, as the amount of meal of the higher or long time high protein wheat is reduced in the blend the time or "quality" of the mixture is correspondingly reduced, or vice versa. Further studies are essential before this principle can be definitely established; however, in view of the fact that the data presented measured well up to mathematical expectations, the miller seems warranted in at least giving the time test a thorough trial as a basis for blending.

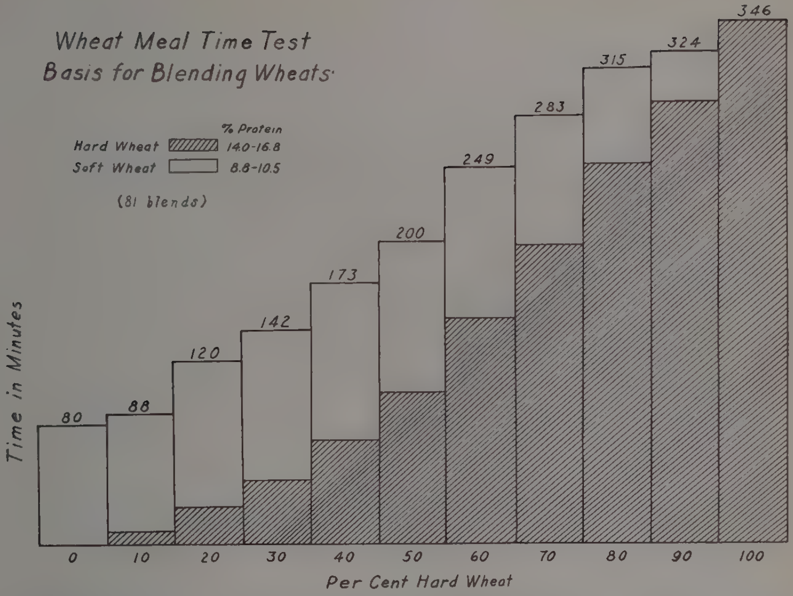

Fig. 11. Blending tests. The bars on the extreme left and right represent the quality "fermentation time" of soft and hard wheats respectively; those in between show the quality "fermentation time" of these wheats when blended in different proportions by weight.

Equipment, Supplies and Cost of Operating the Fermentation Time Test:— The equipment necessary for the Fermentation Time Test is as follows:

1. Labconco grinder
2. Fermentation cabinet
3. Beakers (150 c.c. low form)
4. Fahrenheit thermometer
5. Scales or balance
6. Pipette
7. Glass stirring rod
8. Distilled water
9. Spatula
10. Fleishmann's compressed yeast
11. Graduated cylinder (100 c.c.)

The cost of making the doughballs depends upon the number of tests carried out per day. In the Agronomy Department, the cost has been as low as four cents per doughball, when 150 to 200 doughballs were made within a day. This cost does not include overhead on equipment or distilled water.

Limitations and Interpretations

Some limitations in the application of the Fermentation Time Test in measuring "quality" in wheat have already been given. The following points, however, deserve special emphasis:

1. The Wheat Meal Fermentation Time Test measures only the gluten strength of wheat, and gives no information regarding components of quality such as color, fineness or granularity of flour, flour yield, etc. Other specific tests must be used to determine these components of quality.

2. Being an empirical method, the Fermentation Time Test must be followed exactly as given in this circular if comparable results are to be expected.

3. The method is simple, and easily operated, though its very simplicity may easily become a pitfall to the operator who regards it as foolproof. Despite its apparent simplicity, the Fermentation Time Test should be operated with the same meticulous care as the protein test, the baking test, or any other important laboratory test.

4. The Fermentation Time Test can be satisfactorily used in conjunction with the protein test, the viscosity test, the milling and baking, and other tests in obtaining a more complete knowledge of the essential components of quality. It seems quite possible that no single test will measure all of the components of quality, nor will it give all the information that is desired concerning any wheat.

5. The cost of equipment for the Fermentation Time Test is about $250.00. When large numbers of tests are made within the same day, the cost of making an individual doughball is about five cents.

6. A rule of 10 per cent variability from the average is used as a basis of agreement among triplicate doughball tests. Therefore, the fermentation-time of the individual doughballs of a sample of wheat having an average fermentation-time of 30 minutes may vary between 27 and 33 minutes, while another sample with an average fermentation-time of 300 minutes may vary between 270 to 330 minutes. Thus in a weak gluten 30-minute wheat, the individual triplicate doughballs must agree within six minutes, while in the stronger gluten wheats of 300 minutes, the agreement is within 60 minutes.

7. Since wheat continues to improve in quality for some time after harvesting, the writers follow the practice of testing for quality any time after six weeks following wheat harvest.

UNIVERSITY OF ARIZONA
LIBRARY

Circular No. 219 June, 1936

REPORT OF
MOSES FELL ANNEX FARM
BEDFORD, INDIANA

UNIVERSITY OF ARIZONA LIBRARY

JUNE, 1936

The new pavilion provides a comfortable place for agricultural meetings.

Purdue University
Agricultural Experiment Station
Lafayette, Indiana

Hon. Moses F. Dunn

The Moses Fell Annex Farm consisting of 479 acres was received from the Honorable Moses F. Dunn and Antoinette Fell in 1914, and is used by the Purdue University Agricultural Experiment Station for the purpose of making a thorough study of the agricultural problems of southern Indiana. Mr. Dunn not only gave the farm but generously provided for its development so that it might be operated without cost to the taxpayers of the State.

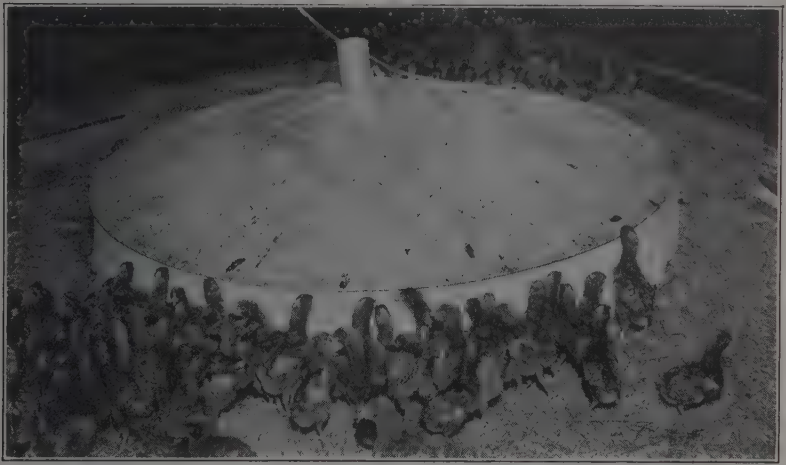
The farm is being operated for the benefit of the farmers of this section. The soil type represents a very large section in the southern part of the state and the results of the experimental work may be applied throughout that section.

Purdue University wishes to acknowledge the helpful cooperation of the various Farm Bureaus, the County Agricultural Agents, the banks, the Home Economics Clubs, Kiwanis Clubs, Rotary Clubs, and other organizations and individuals of Lawrence and neighboring counties. This cooperation extends the value and usefulness of the farm.

REPORT OF MOSES FELL ANNEX FARM

H. J. REED, Farm Director	H. G. HALL, Local Superintendent

During the past year the new pavilion was completed to provide a satisfactory place for agricultural meetings held on the Moses Fell Annex farm. This construction was undertaken in an effort to cooperate with the local authorities to make worthwhile improvements through the provisions of the C.W.A. and the Works Progress Administration. The success of several meetings in the past has been handicapped by inclement weather and those attending the meetings have been somewhat inconvenienced. With this new structure, the usefulness of the farm has been enhanced.



One of the electric brooders used in test on the Moses Fell Annex farm. Five different kinds were used this spring and the results have been quite satisfactory.

Another improvement worthy of note was the 30-foot addition to the cattle barn to provide better facilities for the live stock on the farm. This addition is equipped with modern tie stalls for the cows and will be of interest to farmers handling milk cows.

Several roads on the farm have been improved by a layer of crushed stone to eliminate the muddy conditions that have prevailed in the past.

In cooperation with Professor DenUyl of the Department of Forestry, the woods on the farm have been improved. Many worthless trees have been cut out to give the better kinds a chance to develop. In addition to this, several thousand young trees have been planted to improve the stand and value of the woods in the future.

Ten excellent ewes have been added to the flock of purebred Shropshire sheep through the cooperation and assistance of Professor Claude Harper of the Department of Animal Husbandry. This flock is being developed as a cooperative project on sheep improvement with the Bureau of Animal Industry of the United States Department of Agriculture and it is hoped that this flock may become one of the outstanding flocks of Shropshire sheep in the state.

A purebred Shorthorn bull—Bradford Goldmine No. 83121—was recently purchased for the herd of dual-purpose cattle from one of the old established herds in Pennsylvania. All of his heifers have made the register of merit and have shown good, deep-fleshing qualities. It will be some time before his value can be determined in connection with this project, but if his past performance can be duplicated in this herd we should make marked progress in the improvement of these cattle.

Through the cooperation of the State Department of Conservation, a small flock of pheasants has been established on the farm. The protection and production of wild life in southern Indiana is assuming an important place in an enlarged program of conservation and deserves the interest and cooperation of all citizens.

The Agronomy Department has included a small plot of winter oats in the variety test block for several years. The interest in this crop prompted a larger test of this cereal and last year the four-acre plot produced an average of 52 bushels per acre. A test of three varieties was started this last fall, but the severe winter killed out this larger test. This may be partly due to the fact that the crop was not planted until about the middle of October.

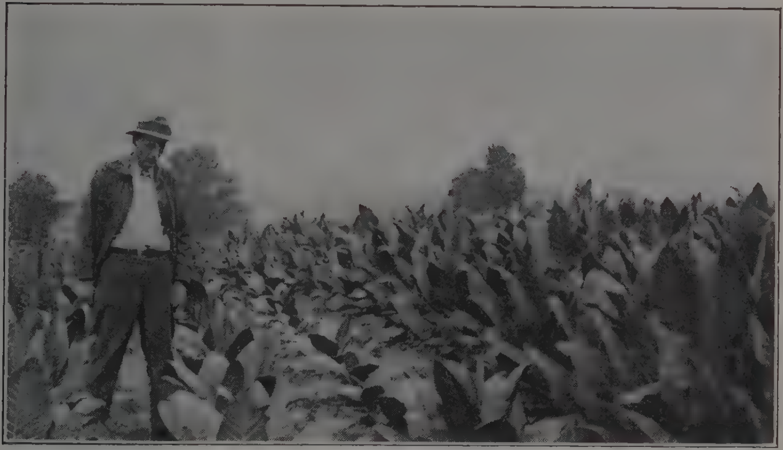
Detasseling plot for the production of hybrid corn.

Winter oats planted in the peach orchard as a cover crop early in September came through the winter in very good condition. A local farmer who purchased seed from the Moses Fell Annex farm and planted it early in September reports that the crop came through the winter in good condition. It is apparent that to be successful in an extremely cold winter these oats should be planted before the middle of September. Many head selections of winter oats were made last year and a few of these have proved hardy in spite of late planting and severe cold. Other selections secured from Tennessee and the U. S. Department of Agriculture show promise of being adapted to southern Indiana. These tests are still in the experimental stage and do not warrant confidence in the adaptability of the crop at this time.

The apple crop last season was the largest that ever was produced on the farm. A good portion of the crop was marketed on the large city markets very satisfactorily, giving further proof that quality fruit produced in southern

Indiana which is well grown, honestly graded and packed can find a market in competition with apples from other production centers.

The severe weather condition in January and February caused extensive winter killing in the peach orchard, many of the trees being entirely killed. Freezing weather during the apple blooming time destroyed much of the fruit prospect for 1936. The Department of Horticulture, however, will go forward with their experimental work and get results of value to apple growers.



Tobacco plots in early August. The plot on the left received no fertilizer and the plot on the right had an application at the rate of 500 pounds per acre.

The poultry work on the farm which has been under the leadership of S. M. Walford of the Department of Poultry Husbandry is being carried forward by Professor Leon Todd. This flock is being improved each year and therefore is becoming increasingly valuable to southern Indiana. Production and feed cost records are kept to show the business side of this enterprise.

The demonstration farm garden project, under the guidance of Professor Gaylord, shows the value of a well grown garden for the farm home. Visit this garden. Planting plans for such a garden are available on request to the Department of Horticulture.

Breeding plots for hybrid corn production are maintained in cooperation with R. R. St. John of the Department of Botany. Interest in hybrid corn has increased very rapidly within the last few years because of the satisfactory performance of hybrids that are adapted to the locality. Years of scientific work are necessary to produce hybrids which meet the requirements of the various sections of this state.

T. E. Heinton of the Department of Agricultural Engineering is continuing the tests with electric brooders for the young chick. The results have been very satisfactory and labor has been utilized more efficiently. Complete cost records are available and will be of interest to poultrymen.

Tobacco experiments are continued on the farm and the results confirm the fact that average yields of 1500 pounds to 1800 pounds of marketable leaf can be produced on this type of soil if fertilized adequately. At least 500 pounds per acre of a good tobacco formula should be applied.

SOILS AND CROPS WORK

The soil fertility experiments carried on under the direction of A. T. Wiancko, Chief, and G. P. Walker, Associate, of the Agronomy Department are showing striking results that are of great value to the farmers of southern Indiana. This phase of the report was prepared by them.

GENERAL SOIL FERTILITY TEST

The field was laid out and tile drained in the spring of 1917. The original rotation was corn, wheat, clover and timothy, but this was changed in 1923 to corn, soybeans, wheat and clover, which is a more suitable rotation for this kind of land. All crops are removed except on plots 6, 7, 8, 10 and 11, where only the ear corn, wheat grain, soybean grain, and clover hay are removed, leaving all the roughage, except the clover hay, on the land in lieu of manure.

The treatments shown in the second column of the table are as follows: L = ground limestone; Res. — crop residue; O = no treatment; M = manure.

All limed plots received 3 tons of ground limestone per acre in the spring of 1917 and an additional 2 tons in 1931. The fertilizers indicated in the table have been applied at the rate of 200 pounds per acre in the row for corn and 400 pounds for wheat since 1929. To the end of 1928 the potash in the fertilizer was 4 per cent and the phosphorus and potash were equally divided between the corn and wheat, but the nitrogen was all applied for wheat, half in the fall and half in the spring.

The manure applications consisted of 6 tons per acre plowed under for the corn in the first round of the rotation. Since then the rate of manuring has been equal to the amount of produce removed during the previous round of the rotation except the wheat grain.

Table I shows the results of different soil treatments begun in 1917.

It will be noted, in comparing with earlier reports and in examining the crops on the experiment field, that the spread between the good and poor treatments is becoming greater year by year, and that the better treatments are becoming more and more profitable. Without soil treatment, the average value of the crops per acre per rotation of corn, soybeans, wheat, and clover, is now $22.39 (plot 14). With lime, manure and fertilizer, the value is $66.50 at an average cash outlay of $9.83 for lime and fertilizer (plot 19).

The most profitable returns have been secured on the limed land, which has received an average of 6.4 tons of manure for corn and 450 pounds of superphosphate per acre divided between the corn and wheat in the rotation of corn, soybeans, wheat, and clover (plot 18). The crop increases from this treatment have averaged 30.7 bushels of corn; 9 3 bushels of soybeans; 12.1 bushels of wheat; and 1925 pounds of hay per acre, valued at $42.89 per rotation at a cash outlay of $9.83 for lime and fertilizer.

Phosphorus is by far the most important plant food need of this soil. Applications of superphosphate have been highly profitable, either alone or in addition to manure. Without manure (plot 2) 225 pounds of 16 per cent superphosphate for corn and for wheat in the four-year rotation has produced average crop increases of 15.9 bushels of corn, 5.2 bushels of soybeans, 8.2 bushels of wheat and 1071 pounds of hay per acre, valued at $24.59, at a cost of $5.04 for the fertilizer. On land receiving an average of 6.4 tons of manure for corn, a similar use of superphosphate has further increased the crop yields by 9.3 bushels of corn, 5.6 bushels of soybeans, and 7.8 bushels of wheat and 1108 pounds of hay, valued at $21.05, at a cost of $5 04 for the phosphate, showing that manure is not sufficient on this land. (Compare plots 16 and 18.)

In recent years, however, potash has become increasingly important on the land which has been receiving only phosphate, showing that the available supply of potash has been so reduced that it has become a limiting factor. It is showing up particularly on the corn and hay. During the last round of the rotation corn has averaged 5.5 bushels more and hay 429 pounds more on plot 3 than on plot 2.

Manure applied at an average rate of 4.7 tons per acre for the corn has produced average crop increases of 15.8 bushels of corn, 1.8 bushels of soybeans, 2.0 bushels of wheat and 399 pounds of mixed hay per acre, valued at $13.53, which amounts to an average return of $2.88 per ton of manure applied. (Compare plots 14 and 15.)

Ground limestone applied at the rate of three tons per acre in 1917 and 2 tons in 1931 has so far produced average crop increases of 5.7 bushels of corn, 1.8 bushels of soybeans, 2.0 bushels of wheat, and 553 pounds of mixed hay per acre, valued at $40.52, up to the present time. (Compare plots 13 and 14.)

Lime and manure together have produced average increases of 21.4 bushels of corn, 3.7 bushels of soybeans, 4.3 bushels of wheat, and 817 pounds of mixed hay per acre, amounting to $21.87 for the rotation. (Compare plots 14 and 16.)

Phosphate and potash on the corn and complete fertilizer on the wheat have produced average increases of 20.0 bushels of corn, 4.4 bushels of soybeans, 10.7 bushels of wheat, and 1254 pounds of mixed hay per acre, amounting to $29.17 at a total cost of $8.40 for the fertilizer. (Compare plots 12 and 14.)

TABLE I—RESULTS OF GENERAL FERTILITY TEST

NOTE.—In computing the financial results, corn has been valued at 55c, wheat at 90c and soybeans at 80c per bushel; and hay at $8.00 per ton. Straw and stover have not been counted. Nitrogen has been charged at 10c, phosphoric acid at 7c and potash at 6c per pound. Ground limestone has been charged at $2.50 per ton. Manure has been charged at 50c per ton for spreading on the land.

Beginning with 1928, the wheat on the west ends of plots 4, 6, 12 and 20 of the General Fertility Test has been given a spring top-dressing of 15 pounds of nitrogen per acre. The average results for the eight years are shown in Table II.

TABLE II—RESULTS OF TOP-DRESSING WHEAT WITH NITROGEN IN SPRING

Plot No.	Treatment	Bushels Wheat Per Acre 1928-1935	Bushels Increase Due to Spring Top-Dressing
4 east end	2-12-6 in fall	15.7	....
4 west end	2-12-6 in fall + 15 lb. N. in April	21.2	5.5
6 east end	2-12-6 in fall	17.3	....
6 west end	2-12-6 in fall + 15 lb. N. in April	23.1	5.8
12 east end	2-12-6 in fall	14.1	....
12 west end	2-12-6 in fall + 15 lb. N. in April	19.5	5.4
20 east end	2-12-6 in fall	18.9	....
20 west end	2-12-6 in fall + 15 lb. N. in April	23.5	4.6

Top-dressing the wheat with 15 pounds of nitrogen per acre in April has increased the yields by 4.6 to 5.8 bushels per acre. This increase has averaged one bushel of wheat for each 2.7 pounds of nitrogen applied. With nitrogen at 10 cents per pound, the increase in yield has been secured at a cost of 27 cents per bushel.

COMPARISON OF DIFFERENT PHOSPHATES

The object of this experiment is to determine the relative values of superphosphate, rock phosphate, bone meal, and basic slag as phosphatic fertilizers. Superphosphate and rock phosphate are also compared in several different proportions with and without lime, manure, nitrogen and potash fertilizers.

This field was laid out and tile drained in the summer of 1915. The crop rotation is corn, wheat and clover, with all produce removed except second growth clover.

The treatments shown in the second column of the table are as follows:
L = ground limestone; M = manure; St.B. = steamed bone meal; BS = basic slag; SP = superphosphate; RP = rock phosphate; N = 12 pounds nitrogen; K = 50 pounds potash.

Ground limestone was applied at the rate of 4 tons per acre in 1915 and an additional 2 tons in 1931.

Manure was applied at the rate of 6 tons per acre for corn in the first round of the rotation and since then in amounts equal to the produce removed except wheat grain. The phosphates are applied at the rate shown in the third column in Table III. The rock phosphate is plowed under for corn, and the other phosphates and the nitrogen and the potash are broadcast and harrowed in before planting. The table shows the results to date of treatments begun in 1916.

The largest returns have been secured from the combination of ground limestone, manure and medium to heavy applications of superphosphate (plots 5 and 26). The heavy treatment (plot 26) has produced average increases of 26.0 bushels of corn, 11.5 bushels of wheat, and 1686 pounds of mixed hay per acre over the average of the untreated land. (Compare plot 26 with 22.)

TABLE III—RESULTS OF PHOSPHATE EXPERIMENT

[1] Plot 13 was manured on Series B in 1916 and Series C in 1917.

[2] Plots 17, 18, 20 and 21 receive 12 pounds of nitrogen and 50 pounds of potash per acre per rotation, all on the corn.

[3] Applied in 1916 and again in 1925 and 1934.

NOTE.—In computing the financial results, corn has been valued at 55c, and wheat at 90c per bushel, and hay at $8.00 per ton. Straw and stover have not been counted. Nitrogen has been charged at 10c, phosphoric acid at 7c and potash at 6c per pound. Rock phosphate (30%) has been charged at $15.00, and ground limestone at $2.50 per ton. Manure has been charged at 50c per ton for spreading on the land.

In combination with lime and manure, superphosphate has been the most profitable source of phosphorus. (Compare plots 5, 3, 2 and 6.) In this comparison, superphosphate, basic slag and steamed bone meal have been applied at the rate of 48 pounds and rock phosphate at 192 pounds of phosphoric acid per acre with manure for each corn crop.

On limed land, superphosphate has been more efficient than rock phosphate in all cases, whether used in large or small amounts, and with or without manure or nitrogen and potash (compare plots 5, 11, 17, 23, 26 and 29 with plots 6, 12, 18, 24, 27 and 30 respectively).

On manured land without lime, rock phosphate has been slightly more profitable than superphosphate (compare plots 8 and 9).

VARIETY TESTS OF FARM CROPS

The selection of hardy, high-yielding varieties of the crops grown in any section is very important. To determine those best adapted for this part of the state, the most promising varieties of several crops have been compared each year for a number of years. Each variety has been harvested separately and the yields determined by weight. The land on which the variety tests are carried has been kept in a good state of fertility by uniform applications of fertilizer on wheat and manure on each corn crop.

PASTURE EXPERIMENTS

The improvement of pasture land has a very definite place in the agricultural program for southern Indiana. Large areas of this section are better adapted to pasture purposes than to its present use. There is a considerable area of pasture land that is not producing in a satisfactory way. The development of better pastures will make possible the expansion of the live stock industry from both the beef cattle and the dairy cattle point of view.

Several years ago a series of pasture plots was laid out in one section of the old pasture, and the results of soil treatment are given in Table V.

Grass mixtures including timothy, red top, Kentucky blue grass, orchard grass, alsike clover, sweet clover, alfalfa, and lespedeza were seeded on the plots in April, 1924. The first two years' growth was largely alsike clover, timothy and red top, with scattered clumps of orchard grass, sweet clover and alfalfa.

After 12 years, blue grass and red top persist along with some timothy on the fertilized plots. Blue grass is much better on the limed and phosphated areas than on the unlimed. Most of the lespedeza, both Korean and common, seemed to have disappeared in the extreme drought of 1930, but is slowly coming back. Hop clover, a member of the clover family, gradually came into the mixtures. This early growing legume seems to have some real worth for rolling pasture land of this type.

For new pasture seedings a mixture of timothy, red top, blue grass, alsike clover and lespedeza is recommended for rolling limestone land. On sour, thin land, a mixture of lespedeza and red top seems best.

TABLE V—RESULTS OF PASTURE EXPERIMENT, 1924-1935

Plot No.	Treatment Per Acre*	Green forage pounds per acre 1924	Green forage increase over untreated	1925	Cured forage, pounds per acre re. av. 1926-35	Cured forage increase over untreated

10	Lime, manure	13613	9860		1668	710

* Treatments applied at seeding time in April, 1923, and fertilizer repeated in fall of 1929. Plots 2 and 9 receive top-dressings of 100 pounds of nitrate of soda per acre each spring. Manure is applied each five years.

ROTATION EXPERIMENT

A comparison of clover, alfalfa, sweet clover, Korean lespedeza and timothy in rotation with corn and wheat is being made on 17 quarter-acre plots.

The effect of these crops on succeeding grain crops, their adaptation and dependability as one-year rotation crops, and their productive capacity are being studied.

All plots except those in the lespedeza rotation were limed with three tons of ground limestone per acre in 1927. All wheat receives 300 pounds per acre of 2-12-6 fertilizer and corn 100 pounds of 0-12-6 in the row. Manure equal to the total weight of produce (except wheat grain) in the previous round of the rotation is divided between corn and wheat. The average results for the first four years are shown in Table VI.

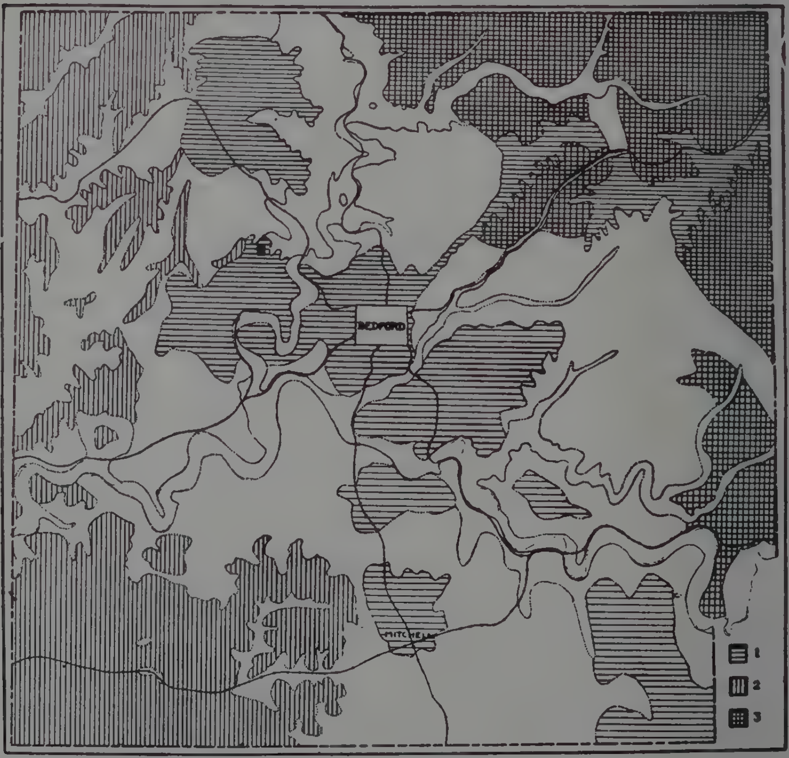
TABLE VI—RESULTS OF CROP ROTATION EXPERIMENTS

Rotations	Average Yields Per Acre, 1932-1935			
	Corn bushels	Wheat bushels	Hay pounds	Legume Seed lbs.
Corn, Wheat, Timothy	33.0	14.3	2274	....
Corn, Wheat, Clover	35.5	19.0	4375	....
Corn, Wheat, Alfalfa	38.2	17.0	1090	....
Corn, Wheat, Sweet Clover	43.3	19.7	....	189
Corn, Wheat, (Sweet Clover Intercrop)	34.7	17.7	....	....
Corn, Wheat, Lespedeza	43.7	16.2	1681	290

It should be noted that the results reported in Table VI cover only the first four years and do not represent a long enough period to warrant definite conclusions.

However, the rotation containing timothy has shown definitely lower corn and wheat yields than those in which legumes are grown.

Map Showing Soil Types Similar to Experiment Field



Region	Principal Soil Characteristics
No. 1.	Yellowish limestone land like Bedford experimental field.
No. 2.	Yellowish "freestone" land.
No. 3.	Like No. 1 on ridge tops and like No. 2 on lower slopes.

Stands of alfalfa seeded in wheat have not been as good as those of clover and sweet clover, which accounts for the low hay yield reported and probably also accounts for the rather low corn and wheat yields in the alfalfa rotation.

The rotation in which lespedeza is used has produced good corn yields in comparison with the rotations where the larger legumes are used. The stand of lespedeza has always been very thick.

The results of the Moses Fell Annex farm can be applied to the greater part of Lawrence County and surrounding territory.

The soil survey made in this county in 1922 enabled the Department of Agronomy to classify the soils of this section and to indicate the types which can benefit most from the experimental work on this farm.

The results will apply to all similar land in the county, which is indicated by shading No. 1 on the map. They will also apply fully as well to the areas indicated by shading No. 2, and more or less fully to the areas indicated by shading No. 3 where the hilltops are like No. 1 and the lower slopes like No. 2.

Portions of the unshaded area would doubtless respond to similar treatments, but most of it does not need either lime or fertilizer to the same extent as the shaded areas.

HORTICULTURAL WORK

The Horticultural Department is carrying on a number of lines of work of special interest to Indiana fruit growers. These projects are under the direction of Dr. Laurenz Greene. Most of the work is being carried out by C. E. Baker, F. C. Gaylord, J. A. McClintock and C. L. Burkholder.

Plum and Prune Variety Block

The first plantings were made in 1929. In most cases three trees of a variety have been considered sufficient for a test of hardiness and regional desirability. Late spring frosts in 1934 and again in 1935 reduced or entirely killed the crop on a number of varieties. It is worth while to note, however, that several varieties such as Stanley, Roberts Prune and French Damson came through these adverse weather conditions with a part or full crop each year. The actual yield by variety of the oldest varieties is shown below:

PRODUCTION RESULTS—1934 AND 1935

Variety	Date Harvested	Age	Number of Gallons		
			1934*	1935**	Number of Trees
Sugar Prune	Aug. 17, 1935	7	0 gals.	30 gals.	3
Bradshaw	Aug. 17, 1935	7	0 gals.	30 gals.	3
Pacific	Aug. 23, 1935	7	0 gals.	14 gals.	3
German Prune	Aug. 23, 1935	7	6 gals.	4 gals.	21
Diamond	Aug. 27, 1935	7	4 gals.	26 gals.	3
Grand Duke	Sept. 5, 1935	7	12 gals.	104 gals.	9
Stanley	Sept. 5, 1935	7	21 gals.	56 gals.	3
French Damson	Sept. 5, 1935	7	75 gals.	46 gals.	21
President	Sept. 5, 1935	7	8 gals.	56 gals.	3
Hungarian Prune	Sept. 5, 1935	7	0 gals.	16 gals.	3
Roberts Prune	Sept. 5, 1935	7	0 gals.	32 gals.	3
Hall Prune	Sept. 5, 1935	7	0 gals.	16 gals.	3
Reine Claude	Sept. 12, 1935	7	4 gals.	32 gals.	21
Yellow Egg	Aug. 23, 1934	7	3 gals.	0 gals.	3
Imperial Epineuse	....	7	0 gals.	0 gals.	12

* A temperature of 26° occurred just after petal fall and is responsible for the low production on some varieties in 1934.

** A temperature of 27° occurred in full bloom in 1935.

It is important that the tops of the tree be properly sprayed if disease and insect control is to be effective. This type of nozzle enables the operator to reach all parts of the tree.

Pear Blight Plot

Almost all pear plantings in the state have been destroyed by pear blight. The two-acre pear planting on the Moses Fell Annex farm has been made with the idea of testing blight resistant root systems, bodies and scaffolds and also to test varieties when grafted on these blight resistant stocks. This planting was made in 1930 and about two-thirds of the trees have now been top-worked and will soon be old enough to begin to set fruit buds.

Codling Moth Control

New methods of codling moth control, especially new and promising spray materials and schedules of application, are being tested each year in this orchard. In 1935 six first brood cover sprays were applied, five of which contained one-half per cent summer oil and lead arsenate. The last application was finished by July 4th and no further insecticidal sprays were applied. In half of the orchard in which one-half pound of soap was used with the arsenate of lead oil combination there was 11/100 of one per cent of infestation in the picked fruit and 53/100 per cent where the soap was omitted.

In 1936 the present plan is to use a new type of calcium arsenate and zinc arsenate in place of lead arsenate after the third cover spray on two 10-acre blocks.

Spray Residue

The schedule of six cover sprays, with the last spray finished by July 4th, resulted in higher residue loads than anticipated. The actual 1935 harvest loads on Grimes and Winesap are shown below.

	Grimes		Winesap	
	Av. No. apples per pound		Av. No. apples per pound	
	4.04		4.07	
	Lead	Arsenic	Lead	Arsenic
Lead-oil	.1210	.0490	.1000	....
Lead-oil-soap	.1962	.0554	.1558	.0531

It was necessary to use 1½ per cent acid at a temperature of 90° to 100° to clean this fruit below the tolerance. All of the crop was put through an underbrush-flood type washer. The time of exposure was usually 20 seconds and it was found that the percentage removal of lead and arsenic was increased very little by using the longer or 30-second gear—the longer exposure being responsible for about a 90 per cent removal compared to 88 per cent removal using the 20-second exposure gear.

Mechanical injury to the fruit was increased by washing, but no injury resulted from the action of the cleaning materials when acid strengths even as high as 2¼ per cent were used at 100° for 20 seconds.

The lead load on this fruit was much more difficult to bring below the federal tolerance than the arsenic. With this fact in mind, two promising non-lead arsenicals will be used on two large blocks of trees in 1936 with the idea of greatly reducing the harvest lead load as well as to study the effect of these sprays on codling moth control and possible injury to the fruit and foliagle of the trees.

Stationary vs. Portable Spraying

In 1929 the north half of the apple orchard was piped for stationary spraying and a new, large-capacity portable rig was purchased to spray the south half of the orchard. During the five-year period 1929-1934 the lowest yearly application cost per 100 gallons of spray for portable spraying was 70 cents and for stationary spraying 50 cents.

In the spring of 1935 the entire orchard was piped and hooked up to the stationary plant. By this new distribution of interest on investment and depreciation over the entire orchard, the cost of spraying the north block was reduced to 34 cents per 100 gallons in 1935 and of the south block to 39 cents, while the cost of spraying the entire orchard was 36⅗ cents per 100 gallons. A reduction of even 30 cents per 100 gallons in spraying costs over the portable method would result in an actual saving of $555.60 in 1935 or nearly one-fourth of the total cost of the complete stationary spraying equipment for the entire orchard.

Peach Orchard

The main area of the peach orchard is now in its eighteenth growing year. The site was never desirable for peach production, and winter injury from time to time has greatly reduced the vigor of the trees. The extremely low temperatures of January, 1936, so severely injured this planting that it is questionable if the older trees are worth an effort to renovate. Nevertheless all but one row of trees were pruned during the week of May 10th and each tree was given nitrate application earlier in the season.

Farm Garden

A good layout for a farm garden is demonstrated in a practical way by Mr. Hall and Mr. Gaylord. The garden plot is divided into two nearly equal plots. One-half is manured and planted to soybeans each year and the following season this area is planted in vegetables, and the other half receives the manure-soybean treatment.

An attempt will be made in 1936 to operate a small irrigation system. using the stationary spray plant to supply the water pressure.

Apple Storage Work

Investigations in the management of an experimental air-cooled apple storage have shown that in the latitude of Bedford and the southern third of the state, high fall temperatures make such storages impractical for use with varieties of apples as Jonathan, Grimes and Delicious that ripen previous to October.

Ice has been used in an attempt to reduce these early fall temperatures in a practical way, where a short storage period was desirable to bridge the gap between harvest and cold weather when air-cooled storages can be successfully operated.

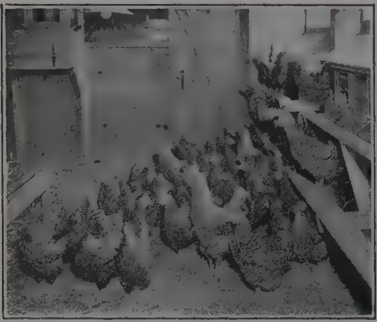
For an average seasonal expenditure of 20.8 cents per bushel it has been possible to secure an average storage temperature of about 45 degrees in an insulated storage room during this warm period prevailing during September and October, which is a reduction of from 10 to 16 degrees over a similar room but uninsulated, cooled by ventilation.

An ice bunker, utilizing cracked ice and salt, has been developed that is considerably more efficient in its use of ice.

By this method it has been possible to prolong the storage period of Grimes and Jonathan until prices have risen sufficiently to make the operation profitable in event of a price rise near the holiday season. Under similar conditions uniced fruit was in poor condition several weeks earlier.

During the past season a small portable humidifyer, operating by a motor-driven air compressor, has given excellent results in maintaining a satisfactory humidity in the ventilated storage room where shriveling of fruit occurs rapidly when dry periods prevail.

POULTRY



The poultry flock, consisting of 800 Barred Plymouth Rock layers and 1,000 growing pullets, has continued to be a practical demonstration of the value of good breeding and management practices. There were 545 pullets housed in the fall of 1935, and of this number 63 laid 150 or more eggs each to April 1st, 1936.

Four special breeding pens were mated, each containing females with records from 210 to 290 eggs, mated to well bred pedigreed males. Approximately 550 individually pedigreed chicks were obtained from these special pens.

A total of 8,071 chicks were started during the past four years. Through the use of a three-year range rotation, testing for Pullorum Disease and adequate equipment, it was possible to raise 95 per cent of the chicks to eight weeks of age. In recent years no fowl paralysis has been detected in the flock.

Records for the past four years show that electric hovers were satisfactory for brooding chicks. Six hovers were used, consuming an average of one-half kilowatt hour of electric energy per chick.

Mr. Stephen M. Walford of the Poultry Extension Division advised regarding the breeding and management of the flock. On February 15, 1936, Mr. Walford resigned and the advisory work is now being done by Leon Todd of the Poultry Extension Division.

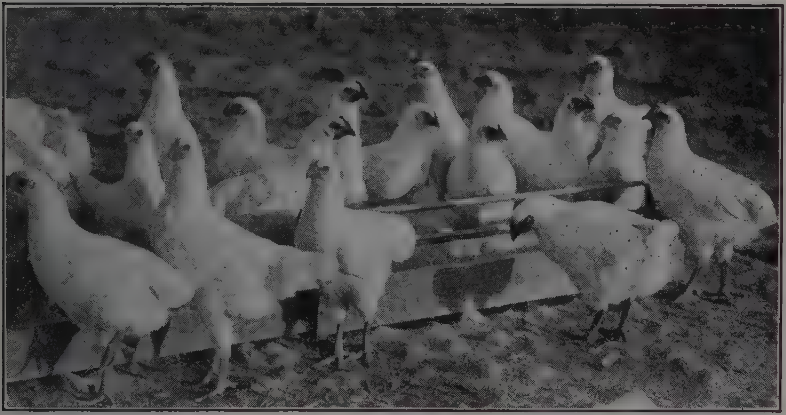
COMMERCIAL FEEDING STUFFS



A Large Tonnage of Poultry Feeds is Sold Each Year. This Publication Reports on the Analysis of Commercial Feeds Inspected by the State Chemist During the Past Year

---

PURDUE UNIVERSITY
AGRICULTURAL EXPERIMENT STATION
LAFAYETTE, IND.

Otis Sidney Roberts, Inspector in the State Chemist Department for more than twenty-eight years including twenty-five years as Chief Inspector and one year as Acting State Chemist, died December 19, 1935. In the passing of Mr. Roberts, the fertilizer, feed and seed industries, as well as the Agricultural interests of Indiana, have suffered a distinct loss of a loyal friend and an able worker.

Herein is presented a condensed report of the commercial feed inspection in Indiana for the year 1935.

Table 1 shows the estimated tonnage based on the sale of inspection tags and the retail value of each class of feed sold in Indiana in 1935.

Table 2 gives the estimated annual total tonnage and expenditures for commercial feeding stuffs since 1911.

Table 3 shows the shipments withdrawn from sale and the reasons for taking such action.

Table 4 states the names and addresses of the manufacturers whose feeds were sampled and analyzed in 1935 and the number of samples passed and not passed.

Table 5 gives the calcium and phosphorus content of feeding stuffs.

Table 6 contains the analyses of cereals and by-products for formulating guarantees.

Definitions of the various classes of feeding stuffs and explanation of the terms used in the analysis of them are given.

COMMERCIAL FEEDING STUFFS

H. R. KRAYBILL, State Chemist
P. B. CURTIS, Associate Chemist O. S. ROBERTS,* Chief Inspector
Assistant Chemists, C. C. Yund, G. E. Halliday, D. M. Doty
Assistant Inspectors, C. M. Cohee, J. W. Jackman

The manufacture and distribution of commercial feeding stuffs have reached large proportions. The increased use of such feeds has been due largely to the demand for balanced rations created by greater knowledge of feed values and of the varied requirements of livestock. In order to furnish information and protection to purchasers of commercial feeds, the Indiana feeding stuffs control law was enacted in 1907. This law is essentially a correct labeling law. It requires the feed manufacturer to label each sack or container of concentrated commercial feeding stuff, sold or offered for sale in Indiana, with an Official Indiana State tag showing the minimum percentage guarantees of crude protein and crude fat, a maximum percentage guarantee of crude fiber and the specific name of each ingredient used in preparing the feed. The term "Concentrated commercial feeding stuff" includes all feeding materials used for food for domestic animals, condimental feeds, poultry feeds, and stock feeds but does not include straw, unmixed whole seeds, unmixed whole grains and unmixed meals made from whole seeds or grains. Before Indiana tags or labels can be issued for a brand of feed it must be registered with the State Chemist.

There is no registration fee but a minimum order for Indiana tags of $5.00 must accompany each certificate of registration. In mineral feeds for which no nutritional properties other than those of a mineral nature are claimed, the usual chemical guarantees need not be stated. However, a declaration should be made of each ingredient contained therein and the minimum percentages of calcium (Ca), phosphorus (P), iodine (I), and the maximum percentage of salt (NaCl). These percentages must also be stated when mixed feeds contain both feed and more than 5 per cent of total mineral ingredients.

AMENDMENT OF FEEDING STUFFS LAW

The Indiana Feeding Stuffs Law as amended in 1933 permits the manufacturer or agent desiring to sell any concentrated commercial feeding stuff in packages or containers of five pounds or less to register such feeding stuff under an annual registration fee of $20.00. If this method of registration is chosen it is unnecessary for the manufacturer to attach an Indiana State label to each container of five pounds or less but it is necessary that the same information as required on the Indiana tag be stated on the private label or wrapper of the container. Appropriate Official Indiana tags or labels must always be attached to all containers over five pounds. Copies of circular 75 entitled "The Feeding Stuffs Control Law and How to Comply with It" may be procured by making application to the State Chemist.

ESTIMATED SALES OF COMMERCIAL FEEDING STUFFS IN 1935

During the year 1935, 2,827 samples were collected from all parts of the State. One inspection sample was secured from approximately each 154 tons of commercial feed sold in Indiana. This is computed from the estimated tonnage shown in Table 1. Based on the sale of Official State tags it is estimated that 436,219 tons of commercial feed with a retail value of $18,255,212 were sold in the State during the year 1935. Compared with the sales of 1934 there was an increase of 23 per cent in tonnage and a corresponding increase of 39 per cent in expenditures. In practically all classes of feed there were greater tonnages sold but the greatest percentage increases in tonnage were for soybean oil meal, brewers and distillers dried grains, proprietary feeds, cottonseed meal, dried and condensed milk products and poultry mash in the order named.

---

*Deceased December 19, 1935.

From Table 2 it may be seen that the total tonnage of all classes of feed sold in 1935 was the highest since 1930 and was almost identical with that sold in 1927 although the total expenditures were not nearly so great.

TABLE 1—Estimated Sales of Commercial Feeding Stuffs in Indiana.

KIND OF FEED	Estimated Tons			Estimated Retail Values, Dollars	
	1933	1934	1935	1934	1935
Alfalfa meal and leaf meal	3,125	3,313	4,531	108,666	165,835
Animal by-products (tankage, meat scraps, etc.)	38,531	39,313	36,438	1,486,031	1,588,697
Brewers', distillers' and yeast dried grains	1,750	1,969	5,031	62,220	143,384
Condimental poultry and stock feeds*	625	688	656	98,590	109,552
Corn feed meal	1,313	1,250	875	34,375	28,700
Corn germ meal	188	813	656	24,390	20,336
Corn gluten meal and feed	1,969	2,594	1,875	86,380	66,000
Corn and oats chop and miscellaneous chops	3,219	4,406	2,656	132,180	94,022
Cottonseed meal	5,875	4,625	7,875	177,600	291,375
Dried buttermilk, dried skimmed milk, condensed, etc.	8,375	4,531	7,344	421,836	757,901
Hominy meal and hominy feed	28,000	42,250	40,250	1,233,700	1,384,600
Linseed oil meal	3,782	3,563	4,406	153,209	169,631
Mill by-products—wheat bran, middlings, rye feeds, etc., with and without screenings	94,438	96,125	96,625	2,917,394	2,947,063
Mineral feeds	3,719	3,063	3,906	177,654	234,360
Oat meal by-products—oat shorts, oat hulls, oat middlings, oat groats, etc.	1,313	1,375	969	37,537	27,132
Poultry scratch feed—with and without grit	14,938	15,281	19,750	531,779	853,200
Poultry mash	82,938	91,938	136,344	3,852,202	6,476,340
Proprietary feeds—					
Cattle and dairy feeds	12,906	21,625	33,625	730,925	1,163,425
Hog and pig meals	7,406	6,875	18,688	294,250	882,074
Horse and mule feeds	719	1,750	2,063	58,275	80,457
Small animal and pet feeds (rabbit, dog, etc.)	2,656	2,656	3,125	229,213	428,125
Calf meals	438	500	906	37,000	60,702
Sheep feeds	63	31	313	1,085	14,711
Soybean oil meal	938	1,031	5,906	43,096	206,710
Miscellaneous—beet pulp, rice bran, processed garbage, sunflower seed oil meal, kelp, peanut oil meal, etc	3,094	3,000	1,406	158,700	60,880
Totals†	322,318	354,565	436,219	13,088,287	18,255,212

*Not all condimental feeds come under the law.
†Does not include feeds registered under annual registration fee.

RESULTS OF INSPECTION

All of the 2,827 official samples were examined microscopically in order to check the ingredients and 2,532 were analyzed chemically for percentages of moisture, crude protein, crude fat, crude fiber, ash and nitrogen free extract. Forty-six samples of mineral feed were analyzed for lime (CaO), phosphoric acid (P_2O_5), iodine (I) and salt (NaCl) content. Of the 2,827 samples examined, 476 of them were found to be technically misbranded while only 300 of them were classified as being seriously deficient or misbranded. This latter group of samples representing 10.6% of the total samples are listed in Table 4 under the heading of "Number of Samples Not Passed". This record is similar to that of the previous year.

REFUNDS AND WITHDRAWALS FROM SALE

Shipments or batches of feed found to be seriously misbranded or deficient were removed from sale immediately and the manufacturers were required to replace or rebuild such deficient lots to meet their guarantees or relabel them with correct guarantees. Where deficient feed had already been sold, refunds were made to the dealers and consumers. In some instances where no records

TABLE 2—Summary of the Annual Tonnage and Expenditures for Commercial Feeding Stuffs Since 1911

YEAR	1911	1912	1913	1914	1915
Estimated Sales, tons	179,000	196,752	217,689	271,751	270,339
Estimated Retail value, dollars	5,056,906	6,371,571	6,406,645	8,461,751	8,221,684
YEAR	1916	1917	1918	1919	1920
Estimated Sales, tons	317,664	379,152	439,152	506,958	390,078
Estimated Retail value, dollars	10,316,516	21,700,101	26,717,086	33,013,463	27,014,049
YEAR	1921	1922	1923	1924	1925
Estimated Sales, tons	283,256	340,197	389,971	419,441	408,713
Estimated retail value, dollars	11,716,745	14,244,175	18,026,682	19,720,313	20,945,026
YEAR	1926	1927	1928	1929	1930
Estimated Sales, tons	337,298	440,534	524,476	498,887	512,096
Estimated retail value, dollars	16,837,512	24,173,605	29,818,566	26,491,777	24,293,652
YEAR	1931	1932	1933	1934	1935
Estimated Sales, tons	322,125	244,909	322,318	354,565	436,219
Estimated retail value, dollars	11,939,153	6,853,043	10,373,772	13,088,287	18,255,212

of the consumers were kept the refunds were turned over to a local charitable organization in the particular community in which the feed was sold. In all cases receipts were required to be filed with the State Chemist. The sum of $819.96 was refunded on 78 shipments or batches of feed by 47 different feed manufacturers. Of the 78 shipments or batches, 37 of them were either tankage or meat and bone scraps. Other most common classes of feed represented in the refunded group include cottonseed meal, alfalfa leaf meal, poultry mash, dairy feed, hog feed and condensed buttermilk. While the payment of a refund does not remove the violation it does indicate the manufacturer's willingness to do what he can to compensate the purchaser for the deficiency.

The most frequent violation of the Indiana Feeding Stuffs Law is in the matter of non-tagging (Table 3). Of the 472.6 tons of commercial feed withdrawn from sale, 369.7 tons were removed because of the absence of Indiana State tags. Proper tagging of feeding stuffs cannot be emphasized too

TABLE 3—Withdrawals From Sale

Number of Shipments Withdrawn from Sale	Number of Manufacturers Represented	REASONS FOR WITHDRAWAL FROM SALE	Amount Withdrawn Tons
222	135	Not tagged	369.7
34	30	Misbranded	32.7
27	19	Deficient in crude protein	62.9
5	3	Deficient in crude protein and crude fat	3.9
2	2	Mutilated tags	2.4
1	1	Short weight	1.0
291	190	Totals	472.6

strongly. Neglect on the part of the manufacturer, distributor, or dealer in attaching the official tag to each bag of feed may lead to serious violations of the Indiana Feeding Stuffs Law. On conviction the penalty of such violations is fifty dollars for the first offense and one hundred dollars for each subsequent offense.

RESULTS OF INSPECTION OF CANNED DOG FOOD

During the year 1935, 53 samples of canned dog and cat food were analyzed. Practically all of these products were registered under the annual registration fee method. Of the 53 samples, 16 of them were found to be seriously misbranded. The average analysis of the 53 samples and the range in analyses are as follows:

Moisture	73.1%	(61.1—79.9)
Protein	9.9%	(4.8—17.3)
Fat	3.3%	(0.8—11.0)
Crude Fiber	0.7%	(0.3— 1.5)
Ash	1.9%	(0.7— 8.0)
Nitrogen Free Extract	11.1%	(3.1—15.3)

Table 4 gives the standing of the various feed manufacturers whose feeds were inspected during the year 1935. This summary of feed inspection may be of considerable value to purchasers of commercial feeds in that it shows just how careful the different manufacturers were in maintaining their guarantees and also in tagging their feeds.

Ziliak & Schafer Milling Co., Haubstadt, Ind.	3	3		
Zionsville Grain Co., Zionsville, Ind.	9	9		

ATTENTION MANUFACTUERS, DEALERS AND CONSUMERS!

Shipments of commercial feeding stuffs made to manufacturers in Indiana to be used for the purpose of mixing feeding stuffs are not required to be registered and tagged with Indiana tags when such manufacturers use these products only as ingredients in the mixing of feeding stuffs that are properly registered in Indiana or when such manufacturers have those ingredients registered in Indiana under their own name.

Shipments of commercial feeding stuffs made to manufacturers who do custom mixing or who offer such feeding stuffs for resale must be registered in Indiana and properly tagged, unless such manufacturers have such feeding stuffs registered under their own name.

Batch mixing is permitted without registering and tagging of the final product, only when the purchaser or his agent actually comes to the mixing plant, makes a bona fide purchase of properly tagged ingredients, sees them before the mixing is done, and also assures himself that they are mixed according to the formula furnished. Unless the above conditions are fulfilled, all feed mixed according to formulas submitted must be registered for sale in Indiana and properly tagged with Official Indiana State tags.

Feeds sold or offered for sale in containers of five pounds or less and registered under the annual registration fee method need not be labeled with Indiana State labels but the same information as required on the Indiana tag must be stated on the container.

When commercial mixed feeds contain less than 20% of a concentrate composed of a large number of ingredients the exact percentage of the concentrate must be stated.

When commercial mixed feeds contain materials of little or no feeding value the exact percentage of each such material must be stated by the manufacturer. This group of materials includes cottonseed hulls, rice hulls, peanut

TABLE 5—Calcium and Phosphorus Content of Feeding Stuffs.

MATERIAL	Calcium (Ca)%	Lime (CaO)%	Phosphorus (P)%	Phosphoric Acid ($P_2O\%_5$)
Alfalfa meal	1.22	1.70	0.23	0.53
Brewers' dried grains	0.16	0.22	0.45	1.03
Buttermilk dried	2.43	3.40	0.96	2.20
Corn	0.01	0.02	0.28	0.65
Corn gluten feed	0.25	0.35	0.27	0.62
Cottonseed meal	0.26	0.37	1.26	2.89
Cowpeas	0.10	0.14	0.45	1.02
Distillers' grain corn	0.04	0.06	0.29	0.67
Fish meal (20.0% ash)	6.65	9.30	3.50	8.00
Hominy feed	0.03	0.04	0.45	1.03
Linseed oil meal	0.36	0.51	0.72	1.65
Malt sprouts	0.15	0.21	0.70	1.61
Meat and bone scraps (30.0% ash)	11.18	15.64	5.06	11.58
Meat scraps (22.0% ash)	8.19	11.46	3.71	8.49
Oats	0.10	0.14	0.37	0.85
Skimmed milk dried	1.29	1.80	0.96	2.20
Soybeans	0.21	0.29	0.60	1.37
Soybean oil meal	0.27	0.38	0.76	1.75
Tankage digester (20.0% ash)	7.10	9.93	3.21	7.35
Wheat	0.04	0.06	0.38	0.86
Wheat bran	0.09	0.13	1.20	2.74
Wheat middlings	0.07	0.10	0.90	2.06
Wheat red dog flour	0.12	0.17	0.85	1.95
Bone meal steamed	28.60	40.00	13.11	30.00
Bone black	28.60	40.00	13.11	30.00
Dicalcium phosphate	22.88	32.00	17.48	40.00
Rock phosphate	28.60	40.00	13.11	30.00
Super phosphate 16%	17.16	24.00	6.99	16.00
Super phosphate 20%	17.88	25.00	8.74	20.00
Phosphatic limestone	35.75	50.00	4.37	10.00
Limestone (95% calcium carbonate)	37.90	53.00	....	....
Oyster shells (95% calcium carbonate)	37.90	53.00	....	....
Wood ashes	21.45	30.00	....	....
Gypsum	25.03	35.00	....	....

shells, corn cob meal, oat hulls, clipped oat by-product, screenings refuse and other similar substances.

When registering mineral feeds manufacturers should note the following change which is to become effective not later than January 1, 1937. Instead of guaranteeing minimum percentages of lime (CaO) and phosphoric acid (P_2O_5), it will be necessary to state minimum percentages of calcium (Ca) and phosphorus (P). To derive these percentages the percentage of lime (CaO) must be multiplied by 0.7 and the percentage of phosphoric acid (P_2O_5) by 0.44. Table 5 gives the calcium and phosphorus content of the mineral ingredients and also the more common feed ingredients.

Table 6, entitled "Analyses of Cereals and By-Products", may also be helpful to manufacturers in calculating safe guarantees for their feed formulas. Although the percentages of Ash and Nitrogen Free Extract are not required on the official tag they are included in Table 6 for reference purposes.

TABLE 6—Analyses of Cereals and By-Products

MATERIAL	POUNDS IN ONE HUNDRED				
	Crude Protein	Crude Fat	Crude Fiber	Ash	Nitrogen Free Extract
Alfalfa leaf meal	20.0	2.5	18.0	12.0	40.0
Alfalfa meal	13.0	1.5	33.0	9.0	35.0
Alfalfa stem meal	9.0	0.8	40.0	7.5	32.0
Barley	11.0	1.8	6.0	2.5	69.0
Beet pulp	8.5	0.9	19.0	3.5	59.0

Sunflower seed	16.0	19.0	30.0	3.0	22.0
Sunflower seed oil meal	21.0	10.0	32.0	4.0	28.0
Tankage 60% protein	60.0	6.0	3.0	20.0	2.0
Velvet bean feed	19.0	4.0	17.0	4.0	48.0
Wheat	12.0	2.0	2.4	1.9	71.0
Wheat bran soft	14.5	3.5	10.0	6.0	56.0
Wheat standard middlings	16.0	4.0	9.5	4.5	56.0
Wheat flour middlings	16.0	4.0	6.0	3.5	60.0
Wheat white middlings	14.0	3.0	3.5	1.5	68.0
Wheat reddog flour	15.0	3.0	4.0	1.5	67.0
Wheat low grade feed flour	12.0	1.5	1.5	1.0	74.0
Wheat mixed feed	15.0	3.5	8.5	5.0	58.0
Whey dried	12.0	0.5	....	8.0	72.0

METHOD FOR CALCULATING CHEMICAL ANALYSIS GUARANTEE OF A MIXED FEED

Ingredients in Batch of Feed	Pounds	Pounds of Protein	Pounds of Fat	Pounds of Fiber
Ground yellow corn	400	38.00	16.00	8.00
Soft wheat bran	100	14.50	3.50	10.00
Wheat flour middlings	100	16.00	4.00	6.00
Meat and bone scraps	75	37.50	4.50	2.25
Dried buttermilk	35	11.20	1.75	......
Alfalfa leaf meal	40	8.00	1.00	7.20
	750	125.20	30.75	33.45

Explanation—

(1) List the ingredients and amount of each used in batch.

(2) By using the information in Table 6 calculate the number of pounds of protein, fat and fiber furnished by each ingredient.
Example—400 lbs. of corn × 9.5% protein in corn = 38.00 lbs. of protein in 400 lbs. of corn.

(3) The sum of each column gives the total number of pounds of protein, fat and fiber in the particular batch.

(4) By dividing each total by the total pounds in the batch, the percentages of protein, fat and fiber are obtained.

Example—$\frac{125.20 \times 100}{750} = 16.7\%$ protein

$$\frac{30.75 \times 100}{750} = 4.1\% \text{ fat}$$

$$\frac{33.45 \times 100}{750} = 4.4\% \text{ fiber}$$

From these percentages a safe guarantee would be 16.5% protein, 4.0% fat and 4.5% fiber.

It is important that all of the terms used in the analysis of feeding stuffs and also the definitions of the various classes of feeding stuffs be thoroughly understood by the feed trade; therefore, this information is given in detail on the remaining pages of this circular.

EXPLANATION OF TERMS USED IN THE ANALYSIS OF FEEDING STUFFS

Moisture is the varying quantity of water occurring in feeding stuffs which can be driven off by heat at the temperature of boiling water. The amount of water present varies with the temperature, moisture content of the air, processes of manufacture and the character of the substance. In most concentrates this value ranges from 5 to 15 per cent.

Crude Fat consists mainly of fats and oils with small amounts of waxes, resins, coloring matter and similar substances, dissolved from feeding stuffs by dry ether. In calculating the heat and energy value of a feed, the fat is considered 2.25 times greater than that of either carbohydrates or protein.

Crude Protein is the term applied to the nitrogenous constituents of a feeding stuff. It is obtained by multiplying the total nitrogen by 6.25. Protein is the most important as well as the most costly constituent in a feed. Plants have the power of building up protein from the inorganic elements of the soil and air while animals must secure their protein from the plants or other animals. The plant proteins contain varying amounts of the essential amino acids; therefore, it is necessary to carefully select a variety of feeds which will furnish the essential amino acids economically.

Crude Fiber is the woody portion of a feeding stuff, for the most part cellulose, and is insoluble in dilute acids and alkalis. Most of the common seeds and grains contain very little fiber while the hulls, husks and stems are high in this constitutent. In poultry and swine, crude fiber, when present in considerable quantities, exerts a retarding influence on the digestion of nutrients present.

Ash, the mineral matter of plants, is the residue left after burning a feeding stuff at low redness. It consists chiefly of the phosphates, sulphates, chlorides and carbonates of sodium, potassium, calcium and magnesium. The calcium and phosphorus are absolutely essential for the proper nutrition of the animal.

Nitrogen Free Extract consists of sugars, starches, pentoses, non-nitrogenous organic acids, etc., and is determined by subtracting the sum of moisture, crude fat, crude protein, crude fiber and ash from 100.

Carbohydrates is the sum of the crude fiber and nitrogen-free extract.

DEFINITIONS OF FEEDING STUFFS*

ALFALFA PRODUCTS

1. **Chopped Alfalfa** is the entire alfalfa hay, chopped and not ground finely enough to become a meal. It must not contain an admixture of alfalfa straw or other foreign material. (Adopted prior to 1928).

2. **Alfalfa Meal** is the product obtained from the grinding of the entire alfalfa hay, without the addition of any alfalfa stems, alfalfa straw or foreign material, or the abstraction of leaves. It must be reasonably free from other crop plants and weeds, and must not contain more than 33 per cent of crude fibre. (Adopted 1928).

3. **Alfalfa Leaf Meal** is the ground product consisting chiefly of leafy materials separated from alfalfa hay. It must be reasonably free from other crop plants and weeds and must not contain more than 18 per cent of crude fibre. (Adopted 1928).

4. **Alfalfa Stem Meal** is the ground product remaining after the separation of the leafy material from alfalfa hay or meal. It must be reasonably free from other crop plants and weeds. (Adopted 1928).

ANIMAL PRODUCTS

5. **Blood Meal** is ground, dried blood. (Adopted 1926).

6. **Blood Flour** is dried blood, prepared by special processes and reduced to a fine powder. (Adopted prior to 1928).

7. **Digester Tankage, Meat Meal Tankage or Feeding Tankage** is the residue from animal tissues exclusive of hoof, horn, manure and stomach contents, except in such traces as might occur unavoidably in good factory practice, especially prepared for feeding purposes by tanking under live steam or by dry rendering or a mixture of the products made suitable by drying and grinding. It must not contain more than 10 per cent of phosphoric acid (expressed as P_2O_5). If it bears a name descriptive of its kind, composition or origin, the material must correspond thereto. (Adopted 1928—Amended 1933).

8. **Digester Tankage with Bone, Meat and Bone Meal Digester Tankage, Meat and Bone Meal Tankage, or Feeding Tankage with Bone** is the residue from animal tissues exclusive of hoof, horn, manure and stomach contents, except in such traces as might occur unavoidably in good factory practice, especially prepared for feeding purposes by tanking under live steam or by dry rendering or a mixture of the products made suitable by drying and grinding, and containing more than 10 per cent of phosphoric acid (expressed as P_2O_5). If it bears a name descriptive of its kind, composition or origin, it must correspond thereto. (Adopted 1928—Amended 1933).

9. **Meat Scraps** is the ground, dry-rendered residue from animal tissues exclusive of hoof, horn, manure and stomach contents. except in such traces as might occur unavoidably in good factory practice. When this product contains more than 10 per cent of phosphoric acid (expressed as P_2O_5), it shall be designated Meat and Bone Scrap. If it bears a name descriptive of its kind, composition or origin it must correspond thereto. (Adopted 1928).

10. **Raw Bone Meal** is the dried, ground product suitable for animal feeding, obtained by cooking in water at atmospheric pressure, undecomposed bone, just enough to remove excess fat and meat. It must not contain less than 23 per cent of protein. (Adopted 1929).

11. **Steamed Bone Meal** is the dried. ground product suitable for animal feeding, obtained by cooking bones with steam under pressure. (Adopted 1929).

12. **Special Steamed Bone Meal** is the dried, ground product suitable for animal feeding, obtained by cooking dried bone after the removal of grease and meat fibre with steam under pressure in the process of obtaining gelatine or glue. (Adopted 1929).

---

*These definitions have been adopted by the Association of American Feed Control Officials.

APPLE PRODUCTS

13. **Dried Apple Pomace** is the sound, dried residue obtained by the removal of cider from apples. (Adopted 1929).

14. **Dried Apple Pectin Pulp** is the sound, dried residue obtained by the removal of pectin from apple products. (Adopted 1929).

BARLEY PRODUCTS

15. **Barley Hulls** is the product consisting of the outer coverings of the barley. (Adopted prior to 1928).

16. **Barley Feed** is the entire by-product resulting from the manufacture of pearl barley from clean barley. (Adopted prior to 1928).

17. **Barley Mixed Feed** is the entire offal from the milling of barley flour from clean barley and is composed of barley hulls and barley middlings. (Adopted prior to 1928).

18. **Ground Barley** is the entire product obtained by grinding clean sound barley, containing not less than 90 per cent of pure barley and not more than 10 per cent of other grains, weed seeds and other foreign material and not more than 6 per cent of crude fibre; provided that no portion of this stated 10 per cent of other grains, weed seeds or other foreign material shall be intentionally added. (Adopted prior to 1928).

19. **Mixed Feed Barley** is the entire product obtained by grinding country run barley containing not less than 75 per cent of pure barley and not more than 25 per cent of other grains, weed seeds and other foreign material; provided that no portion of this stated 25 per cent of other grains, weed seeds or foreign material shall be intentionally added. The ingredients must be stated as barley, other grains, weed seeds and foreign material. (Adopted prior to 1928).

BEET PRODUCTS

20. **Dried Beet Pulp** is the dried residue from sugar beets which have been cleaned and freed from crowns, leaves and sand, and from which the sugar has been extracted. (Adopted prior to 1928).

BREWERS' AND DISTILLERS' PRODUCTS

21. **Brewers' Dried Grains** is the dried residue obtained in the manufacture of beer. (Adopted prior to 1928).

22. **Distillers' Corn Dried Grains or Distillers' Rye Dried Grains** is the dried residue obtained in the manufacture of alcohol and distilled liquors. The product must bear the designation indicating the cereal predominating. (Adopted prior to 1928).

23. **Distillers' Corn Solubles** is a by-product from the manufacture of alcohol from corn solids obtained by the evaporation of the mash liquor after the removal of the alcohol and wet grains. (Adopted prior to 1928).

24. **Distillers' Rye Solubles** is a by-product from the manufacture of alcohol from rye solids obtained by the evaporation of mash liquor after the removal of the alcohol and wet grains. (Adopted prior to 1928).

25. **Distillers' Corn and Rye Solubles** is a by-product from the manufacture of alcohol from corn and rye solids obtained by the evaporation of mash liquor after the removal of the alcohol and wet grains. (Adoption prior to 1928).

26. **Malt Sprouts** are the sprouts of the barley grain obtained from malted barley. Sprouts derived from any other malted cereal must be designated by the name of that cereal. (Adopted prior to 1928).

27. **Yeast Dried Grains or Vinegar Dried Grains** is the properly dried residue from the mixture of cereals, malt and malt sprouts (sometimes cottonseed meal) obtained in the manufacture of yeast or vinegar, and consists of corn or corn and rye from which most of the starch has been extracted, together with malt added during the manufacturing process to change the starch

to sugars, and malt sprouts (sometimes cottonseed meal) added during the manufacturing process to aid in filtering the residue from the wort and to serve as a source of food supply for the yeast. (Adopted prior to 1928).

BUCKWHEAT PRODUCTS

28. **Buckwheat Shorts or Buckwheat Middlings** are the portions of the buckwheat grain immediately inside the hull secured after separation from the flour. (Adopted prior to 1928).

CHOP

29. **Chop** is a ground or chopped feed composed of one or more different cereals or by-products thereof. If it bears a name descriptive of the kind of cereals, it must be made exclusively of the entire grains of those cereals. (Adopted prior to 1928).

COCOANUT PRODUCTS

30. **....Per Cent Protein Cocoanut Oil Meal or ....Per Cent Protein Copra Oil Meal** is the ground residue from the extraction of part of the oil from the dried meat of the cocoanut. (Adopted prior to 1928).

CORN PRODUCTS

31. **Corn Meal** is finely ground, unbolted corn. (Adopted prior to 1928).

32. **Corn Bran** is the outer coating of the corn kernel, with little or none of the starchy part or germ. (Adopted 1931).

33. **Corn Feed Meal** is the fine siftings obtained in the manufacture of screened corn chop, screened ground corn or screened cracked corn, with or without its aspiration products added. (Adopted 1931).

34. **Corn Chop, Ground Corn or Cracked Corn** is the entire product made by grinding, cutting or chopping the grains of sound Indian corn, and may be fine, medium or coarse, and must not contain more than 4 per cent of foreign material. (Adopted 1931).

35. **Screened Corn Chop, Screened Ground Corn, or Screened Cracked Corn** is the coarse portion of corn chop, ground corn or cracked corn from which most of the fine particles have been removed. and must not contain more than 4 per cent of foreign material. (Adopted 1931).

36. **Corn Grits or Hominy Grits** is the product consisting of the fine or medium sized, hard flinty portions of sound Indian corn containing little or none of the bran or germ. (Adopted 1931).

37. **Ear Corn Chops** is corn and cob chopped, without the husk, with no greater proportion of cob than occurs in the ear corn in its natural state. (Adopted prior to 1928).

38. **Corn Gluten Meal** is that part of commercial shelled corn that remains after the separation of the larger part of the starch, the germ and the bran, by the processes employed in the manufacture of corn starch. It may or may not contain corn solubles. (Adopted prior to 1928).

39. **Corn Gluten Feed** is that part of commercial shelled corn that remains after the separation of the larger part of the starch and the germs by the processes employed in the manufacture of corn starch. It may or may not contain corn solubles. (Adopted prior to 1928)..

40. **Maltose Process Corn Gluten Feed** is the dried residue from degermed corn. after removal of the starch in the manufacture of malt syrup. (Adopted prior to 1928).

41. **Hominy Feed** is a mixture of corn bran, corn germ and a part of the starchy portion of either white or yellow corn kernels or mixture thereof as produced in the manufacture of pearl hominy, hominy grits or table meal, and shall contain not less than 5 per cent of crude fat. If prefixed with the words "white" or "yellow". the product must correspond thereto. (Adopted 1935).

42. **Corn Oil Cake** consists of the corn germ from which part of the oil has been pressed and is the product obtained in the wet milling process of

manufacture of corn starch, corn syrup, and other corn products. (Adopted prior to 1928).

43. **Corn Oil Meal** is ground corn oil cake. (Adopted prior to 1928).

44. **Corn Germ Cake** consists of corn germ with other parts of the corn kernel from which part of the oil has been pressed, and is the product obtained in the dry milling process of manufacture of corn meal, corn grits, hominy feed, and other corn products. (Adopted prior to 1928).

45. **Corn Germ Meal** is ground corn germ cake. (Adopted prior to 1928).

46. **Corn Screenings** is the product consisting of the small light grains of corn, parts of grains of corn and/or other cereals, and other materials having feeding value, obtained by screening shelled corn, excluding sand, dirt and other similar inert materials. (Adopted 1931).

COTTONSEED PRODUCTS

47. **Cottonseed Meal** is a product of the cottonseed only, composed principally of the kernel with such portion of the hull as is necessary in the manufacture of oil; provided that nothing shall be recognized as cottonseed meal that does not conform to the foregoing definition and that does not contain at least 36 per cent of protein. Cottonseed meal shall be graded and classed as follows: (Adopted prior to 1928).

48. **....Per Cent Protein Cottonseed Meal, Prime Quality.** Cottonseed meal, prime quality, must be finely ground, not necessarily bolted, of sweet odor, reasonably bright in color, yellowish, not brown or reddish, free from excessive lint, and shall contain not less than 36 per cent of protein. It must be designated and sold according to its protein content. Cottonseed meal with 36 per cent of protein must be termed "36 per cent Protein Cottonseed Meal, Prime Quality", and higher grades similarly designated (as "43 per cent Protein Cottonseed Meal, Prime Quality"), etc. (Adopted prior to 1928).

49. **....Per Cent Protein Cottonseed Meal, Off Quality.** Cottonseed meal not fulfilling the above requirement as to color, odor and texture must be graded "36 per cent Protein Cottonseed Meal, Off Quality", and higher grades similarly designated. (Adopted prior to 1928).

50. **Cottonseed Feed** is a mixture of cottonseed meal and cottonseed hulls, containing less than 36 per cent of protein. (Adopted prior to 1928).

51. **....Per Cent Protein Whole Pressed Cottonseed, Prime Quality** is the product resulting from subjecting the whole, sound, mature, clean undecorticated cottonseed to pressure for the extraction of oil, and includes the entire cottonseed less the oil extracted and the lint removed. It must be designated and sold according to its protein content. (Adopted 1932).

52. **....Per Cent Protein Ground Whole Pressed Cottonseed, Prime Quality** is whole pressed cottonseed, ground. It must be designated and sold according to its protein content. (Adopted 1932).

GARBAGE

53. **Processed Garbage** is composed of dried animal and vegetable waste from garbage collected sufficiently often that harmful decomposition has not set in, and separated from material such as crockery and glass. Its odor must not be suggestive of the presence of decomposition and it must contain less than one per cent of glass. None of it shall contain knife-like or needle-like particles, and the maximum percentage of glass should be stated on the label when present in excess of one-fifth of one per cent. (Adopted prior to 1928).

IVORY NUT PRODUCTS

54. **Ivory Nut Meal** is the ground waste material resulting from the manufacture of buttons and similar articles from the vegetable ivory nut. (Adopted prior to 1928).

LINSEED AND FLAX PRODUCTS

55. ....**Per Cent Protein Linseed Cake or Linseed Meal** is the product obtained in the removal of the oil from flaxseed; provided that the final product contains less than 6 per cent of weed seeds and other foreign materials; and provided, further, that no portion of the stated 6 per cent of weed seeds and other foreign materials shall be deliberately added. It shall not contain more than 0.5 per cent of acid insoluble ash. (Adopted 1933).

56. ....**Per Cent Protein Old Process Oil Meal or ....Per Cent Protein Old Process Linseed Meal** is oil meal as defined below, produced by crushing cooking and hydraulic pressure. (Adopted prior to 1928).

57. ....**Per Cent Protein New Process Oil Meal or ....Per Cent Protein New Process Linseed Meal** is oil meal as defined below produced by crushing, heating and the use of solvents. (Adopted prior to 1928).

58. **Flax Plant By-Products** is that portion of the flax plant remaining after the separation of the seed, the bast fibre and a portion of the shives, and consists of flax shives, flax pods, broken and immature flax seeds, and the cortical tissues of the stem. (Adopted prior to 1928).

59. **Ground Flaxseed or Flaxseed Meal** is the product obtained by grinding flaxseed which has been screened and cleaned of weed seeds and other foreign materials by the most improved commercial process; the final product must contain less than 4 per cent of weed seeds and other foreign materials, and no portion of the stated 4 per cent of weed seeds and other foreign materials shall be intentionally added. (Adopted prior to 1928).

60. **Unscreened Faxseed Oil Feed Cake** is the product obtained by extraction of part of the oil from unscreened flaxseed by crushing, cooking and hydraulic pressure, or by crushing, heating and the use of solvents. The ingredients must be stated as "partially extracted flaxseed and foreign seeds (wheat, wild buckwheat, pigeon grass, wild mustard, etc.)". Adopted prior to 1928).

61. **Ground Unscreened Flaxseed Oil Feed** is the ground unscreened flaxseed oil feed cake. (Adopted prior to 1928).

62. **Screenings Oil Feed** is the ground product obtained after extraction of part of the oil by crushing, cooking and hydraulic pressure, or by crushing, heating and the use of solvents from the smaller imperfect flaxseed, weed seeds and other foreign materials having feeding value, separated in cleaning flaxseed. The name of the grain from which the screenings are separated must be prefixed to "screenings oil feed." (Adopted prior to 1928).

63. ....**Per Cent Protein Oil Cake** is the product obtained after the extraction of part of the oil by crushing, cooking and hydraulic pressure, or by crushing, heating and the use of solvents, from flaxseed which have been screened and cleaned of weed seeds and other foreign materials by the most improved commercial process. When used alone the term "Oil Cake" shall be understood to designate linseed cake as defined. When used to cover any other product the name of the seed from which it is obtained must be prefixed to the words "Oil Cake". (Adopted prior to 1928).

64. ....**Per Cent Protein Oil Meal or ....Per Cent Protein Ground Oil Cake** is oil cake ground to a meal. (Adopted prior to 1928).

MARINE PRODUCTS

65. **Fish Meal** is clean, dried, ground tissues of undecomposed whole fish and/or fish cuttings with or without the extraction of part of the oil, and contains not more than 3 per cent of salt (NaCl). If it contains more than 3 per cent of salt (NaCl) the amount of salt must constitute a part of the brand name, provided that in no case shall the salt content of this product exceed 7 per cent. (Adopted 1933).

66. **Fish Residue Meal** is the clean, dried, undecomposed residue from the manufacture of glue from non-oily fish, and contains not more than 3 per cent of salt (NaCl). If it contains more than 3 per cent of salt (NaCl) the amount of salt must constitute a part of the brand name, provided that

in no case shall the salt content of this product exceed 7 per cent. (Adopted 1933).

67. **Crab Meal** is prepared from the undecomposed dried waste of the crab industry and contains the shell, viscera and part or all of the flesh. It contains not less than 25 per cent of protein and not more than 3 per cent of salt (NaCl). If it contains more than 3 per cent of salt (NaCl) the amount of salt must constitute a part of the brand name, provided that in no case shall the salt content of this product exceed 7 per cent. (Adopted 1933).

68. **Shrimp Meal** is prepared from the undecomposed dried waste of the shrimp industry and contains the head, hull and/or the whole shrimp and not more than 3 per cent of salt (NaCl). If it contains more than 3 per cent of salt (NaCl) the amount of salt must constitute a part of the brand name, provided that in no case shall the salt content of this product exceed 7 per cent. (Adopted 1933).

69. **Whale Meal** is prepared from the clean, dried undecomposed flesh of the whale, after part of the oil has been extracted. It contains not more than 3 per cent of salt (NaCl). If it contains more than 3 per cent of salt (NaCl) the amount of salt must constitute a part of the brand name, provided that in no case shall the salt content of this product exceed 7 per cent. (Adopted 1933).

70. **Cod Liver Oil** is the product obtained by extraction of part of the oil from cod livers. (Adopted 1932).

71. **Sardine Oil or Pilchard Oil** is the product obtained by extraction of part of the oil from the whole Pacific sardine or pilchard or from cannery refuse of this species of fish. (Adopted 1932).

72. **Salmon Oil** is the product obtained by extraction of part of the oil from the cannery refuse of salmon. (Adopted 1932).

73. **Tuna Oil** is the product obtained by extraction of part of the oil from the cannery refuse of tuna. (Adopted 1932).

74. **Menhaden Oil** is the product obtained by extraction of part of the oil from whole menhaden. (Adopted 1932).

75. **Herring Oil** is the product obtained by extraction of part of the oil from the whole herring or part of the herring. (Adopted 1933).

76. **Salmon Liver Oil** is the product obtained by extraction of part of the oil from salmon livers. (Adopted 1933).

77. **Stearine** is the solid material obtained by filtration from an animal or vegetable oil after chilling or freezing in the process of refining. When this product is sold as a feed, the term shall be prefixed by the name of the oil from which it is obtained. (Adopted 1934).

MILK PRODUCTS

78. **Dried Buttermilk** is the product resulting from the removal of water from clean, sound buttermilk derived from natural cream to which no foreign substances have been added, excepting such as are necessary and permitted in the manufacture of butter. It contains not more than 8 per cent of moisture, not more than 13 per cent of mineral matter (ash), and not less than 5 per cent of butterfat, as determined by the Roese-Gottlieb method. (Adopted 1932).

79. **Evaporated Buttermilk, Concentrated Buttermilk** or **Condensed Buttermilk** is the product resulting from the removal of a considerable portion of water from clean, sound buttermilk derived from natural cream to which no foreign substances have been added excepting such as are permitted and necessary in the manufacture of butter. It contains not less than 27 per cent of total solids, not less than 2 per cent of butterfat, and not more than .14 per cent of ash for each per cent of solids. This definition does not prohibit the use of a distinctive trade name, provided it is followed by one of the names given. (Adopted prior to 1928).

80. **Dried Skimmed Milk** is the product resulting from the removal of

water from clean, sound skimmed milk. It contains not more than 8 per cent of moisture. (Adopted 1930).

81. **Dried Soured Skimmed Milk** is the product resulting from the removal of water from clean, sound skimmed milk which has been soured by a suitable culture of lactic bacteria. It contains not more than 8 per cent of moisture. (Adopted 1932).

82. **Evaporated Soured Skimmed Milk, Concentrated Soured Skimmed Milk** or **Condensed Soured Skimmed Milk** is the product resulting from the removal of a considerable portion of water from clean, sound skimmed milk which has been soured by a suitable culture of lactic bacteria. It contains not less than 27 per cent of total solids. (Adopted 1932).

83. **Condensed Skimmed Milk** is the product resulting from the removal of a considerable portion of water from clean, sound skimmed milk. It contains not less than 27 per cent of total solids. (Adopted 1930).

84. **Milk Sugar Feed or Dried Whey** is the by-product from the manufacture of cheese and should contain at least 70 per cent of lactose (milk sugar). (Adopted 1932).

85. **Dried Whey** is the by-product from the manufacture of cheese and/or casein. This product shall contain at least 65 per cent of lactose (milk sugar). (Adopted 1934).

86. **Cheese Rind** is cooked, partially defatted cheese rind. (Adopted 1935).

MINERAL FEEDS

87. Mixed feeds containing both feed and more than 5 per cent of mineral ingredients require, in addition to the usual declaration of the chemical feed analysis, a declaration of each ingredient contained therein and the minimum percentages of lime expressed as CaO, phosphoric acid expressed as P_2O_5, iodine (I), and the maximum percentage of salt (NaCl) if same be present. If minerals predominate in the mixture, the usual declaration of the chemical feed analysis, with the exception of protein, may be omitted.

In mineral feeds containing no organic ingredient, the usual chemical feed guarantee need not be made. A declaration should be made of each ingredient contained therein and the minimum percentage of lime expressed as CaO, phosphoric acid expressed as P_2O_5, iodine (I), and the maximum percentage of salt (NaCl) if same be present.

The mineral ingredients should be stated in the common English terms, if any such terms exist.

It being impossible to classify separately the drug ingredients and the mineral ingredients, be it resolved:

(a) That all mixtures containing mineral ingredients generally regarded as dietary factors essential for the normal nutrition of animals and which are sold or represented for the primary purpose of supplying these minerals as additions to rations in which these same mineral factors may be deficient, be classified as mineral feeds.

(b) That all other preparations which are sold or represented primarily for the cure, mitigation or prevention of disease be classified by this Association as drugs, medicines or specifics. (Adopted prior to 1928).

MINERAL FEEDS

(NOTE)—This change is to become effective not later than January 1, 1937.

88. Mixed feeds containing both feed and more than 5 per cent of mineral ingredients require, in addition to the usual declaration of the chemical feed analysis, a declaration of each ingredient contained therein and the minimum percentages of calcium (Ca), phosphorus (P), iodine (I), and the maximum percentage of salt (NaCl) if same be present. If minerals predominate in the mixture, the usual declaration of the chemical feed analysis, with the exception of protein, may be omitted.

In mineral feeds for which no nutritional properties other than those of a mineral nature are claimed, the usual chemical guarantees need not be declared. A declaration should be made of each ingredient contained therein and the minimum percentage of calcium (Ca), phosphorus (P), iodine (I), and the maximum percentage of salt (NaCl) if same be present.

The mineral ingredients should be stated in the common English terms, if any such terms exist.

It being impossible to classify separately the drug ingredients and the mineral ingredients, be it resolved:

(a) That all mixtures containing mineral ingredients generally regarded as dietary factors essential for the normal nutrition of animals and which are sold or represented for the primary purpose of supplying these minerals as additions to rations in which these same mineral factors may be deficient, be classified as mineral feeds.

(b) That all other preparations which are sold or represented primarily for the cure, mitigation or prevention of disease be classified by this Association as drugs, medicines or specifics. (Adopted 1935).

OAT PRODUCTS

89. **Oat Hulls** is the product consisting of the outer covering of the oat. (Adopted prior to 1928).

90. **Oat Middlings** is the product consisting of the floury portions of the oat groat obtained in the milling of rolled oats. (Adopted prior to 1928).

91. **Oat Shorts** is the product consisting of the covering of the oat grain lying immediately inside the hull, being a fuzzy material carrying with it considerable portions of the fine floury part of the groat obtained in the milling of rolled oats. (Adopted prior to 1928).

92. **Oat Chop, Ground Oats, Pulverized Oats, Crushed Oats, or Crimped Oats** consists of the entire product made by chopping, cutting, grinding, crushing, or crimping whole oats. (Adopted 1931).

93. **Oat Groats** are the kernels produced from cleaned and dried oats in the process of manufacturing oat meal. (Adopted 1931).

94. **Hulled Oats, or Undried Oat Groats** are the kernels produced from the undried grain in the process of hulling oats. (Adopted 1931).

95. **Oat Meal, or Ground Oat Groats** is the product produced by cutting, cracking or grinding oat groats. (Adopted 1931).

96. **Rolled Oat Groats or Rolled Oats** is the product obtained in the process of rolling oat groats. (Adopted 1931).

97. **Clipped Oat By-Products** is the by-product obtained in the manufacture of clipped oats. It may contain the light chaffy material broken from the end of the hulls, empty hulls, light immature oats and dust. It must not contain an excessive amount of oat hulls. (Adopted prior to 1928).

98. **Oat Mill Feed** (Oat Hulls, Oat Shorts and Oat Middlings) is the entire by-product produced in the manufacture of oat groats and consists of oat hulls, oat shorts and oat middlings. If used in a mixed feed, it shall be called Oat Mill Feed (Oat Hulls, Oat Shorts and Oat Middlings). (Adopted 1932).

PALM PRODUCTS

99. **Palm Kernel Oil Meal** is the ground residue from the extraction of part of the oil by pressure or solvents from the kernel of the fruit of Elaeis guineensis or Elaeis molanococco. (Adopted prior to 1928).

PEANUT PRODUCTS

100. **....Per Cent Protein Peanut Oil Cake** is the residue after the extraction of part of the oil by pressure or solvents from peanut kernels. (Adopted prior to 1928).

101. **....Per Cent Protein Peanut Oil Meal** is ground peanut oil cake. (Adopted prior to 1928).

102. **Unhulled Peanut Oil Feed** is the ground residue obtained after extraction of part of the oil from whole peanuts, and the ingredients must be designated as **Peanut Meal and Hulls.** (Adopted prior to 1928).

RICE PRODUCTS

103. **Rice Bran** is the pericarp or bran layer of the rice, with only such quantity of hull fragments as is unavoidable in the regular milling of rice. (Adopted prior to 1928).

104. **Rice Hulls** is the product consisting of the outer coverings of the rice. (Adopted prior to 1928).

105. **Rice Polish** is the finely powdered material obtained in polishing the kernel. (Adopted prior to 1928).

106. **Rice Meal** is ground brown rice or ground rice after the hull has been removed. (Adopted prior to 1928).

107. **Ground Rough Rice** is ground rice from which the hull has not been removed or ground paddy rice. (Adopted prior to 1928).

108. **Rice Stone Bran** is the siftings from the materials secured in removing hulls from rice and contains rice germs, broken rice and some rice hulls. (Adopted prior to 1928).

109. **Rice Huller Bran** is a product secured by the huller and cones from brown rice and consist mostly of the bran and germs. (Adopted prior to 1928).

RYE PRODUCTS

110. **Rye Bran** is the course outer covering of the rye kernel as separated from the cleaned and scoured rye. (Adopted prior to 1928).

111. **Rye Feed** is a by-product obtained in the usual process of the milling of rye flour from cleaned and scoured rye grain, consisting principally of the mill-run of the outer covering of the rye grain and the germ with small quantities of flour and aleurone. (Adopted prior to 1928).

112. **Rye Red Dog** is a by-product obtained in the usual process of the milling of rye flour, consisting principally of aleurone with small quantities of flour and fine bran particles and must not contain more than 3.5 per cent of crude fibre. (Adopted prior to 1928).

113. **Rye Low-Grade Feed Flour** consists principally of dark rye flour and small quantities of aleurone and fine bran particles and must not contain more than 1.5 per cent of crude fibre. (Adopted prior to 1928).

114. **Rye Middlings** consists of rye feed and rye red dog combined in the proportions obtained in the usual process of milling rye flour. (Adopted prior to 1928).

115. **Rye Flour Middlings** consist of rye feed, rye red dog and pure dark rye flour combined in the proportions obtained in the milling of rye flour and must not contain more than 5 per cent of crude fibre. (Adopted prior to 1928).

SCREENINGS

116. **Screenings** consist of a mixture of mill or elevator run materials or a combination of varying amounts of materials obtained in the process of cleaning grain and/or seed, such as inferior, light or broken grain or seeds, weed seeds, hulls, chaff, joints, straw, elevator dust, floor sweepings. They must be relatively free of unpalatable or injurious weed seeds, sand and dirt. They must not contain more than 14 per cent of fibre or more than 6.50 per cent of ash. If they bear a name descriptive of their kind or origin, they must correspond thereto. (Adopted 1935).

117. **Screenings—Grain** consist of inferior, light or broken grain and/or seed obtained in the process of cleaning grain or seed or recleaning screennings. They must be relatively free of weed seeds, chaff, straw, hulls, joints, sand and dirt, and other foreign materials. If they bear a name descriptive of their kind or origin, they must correspond thereto. (Adopted 1935).

118. **Screenings Waste or Screenings Refuse** is a mixture of materials of little or no feeding value, or injurious as a feed, obtained in the process of cleaning grain and/or seed, or recleaning screenings, such as weed seeds which may be unpalatable or injurious, chaff, hulls, straw, sticks, joints, elevator dust, floor sweepings, sand and dirt. (Adopted 1935).

119. **Scourings** consist of such portions of the cuticle, brush, white caps, dust, smut and other materials as are separated from the grain in the usual commercial process of scouring. (Adopted prior to 1928).

(NOTE)—If to any of the wheat or rye by-product feeds there should be added screenings or scourings—as above defined, either ground or unground, bolted or unbolted, such brand shall be so registered, labeled and sold as clearly to indicate this fact. The word "Screenings", or "Scourings", as the case may be, shall appear as part of the name or brand and shall be printed in the same size and face of type as the remainder of the brand name. When the word "Screenings" appears it is not necessary to show also on the labeling the word "Scourings". (Adopted prior to 1828).

SORGHUM PRODUCTS

120. **Head Chops** is the product consisting of the entire heads of the grain sorghums chopped, and should bear the name of the sorghum from which it is made. This includes, among others, kaffir head chops, milo head chops, feterita head chops, and sorghum head chops. (Adopted prior to 1928).

121. **Head Stems** is the product consisting of the stems from the heads of the grain sorghums after the grain has been removed, and should bear the name of the sorghum from which it is made. (Adopted prior to 1928).

SOYBEAN PRODUCTS

122. **Ground Soybeans** is the product obtained by grinding whole soybeans without cooking or removing any of the oil. (Adopted 1933).

123. **....Per Cent Protein Soybean Oil Cake or Soybean Oil Chips** is the product obtained by crushing, cooking and removing part of the oil from soybeans. (Adopted 1933).

124. **....Per Cent Protein Soybean Oil Meal** is ground soybean oil cake or ground soybean oil chips. (Adopted 1933).

VELVET BEAN PRODUCTS

125. **Velvet Bean Meal** is ground velvet beans containing only an unavoidable trace of hulls or pods. (Adopted prior to 1928).

126. **Ground Velvet Bean and Pod** is the product derived by grinding velvet beans with the pod. It contains no additional pods or other materials. (Adopted prior to 1928).

WHEAT PRODUCTS

127. **Wheat Bran** is the coarse outer covering of the wheat kernel as separated from cleaned and scoured wheat in the usual process of commercial milling. (Adopted prior to 1928).

128. **Wheat Standard Middlings** consist mostly of fine particles of wheat bran, wheat germ, and very little of the fibrous offal obtained from the "tail of the mill". This product must be obtained in the usual commercial process of milling and must not contain more than 9.5 per cent of crude fibre. (Adopted prior to 1928).

129. **Wheat Flour Middlings** shall consist of wheat standard middlings and wheat red dog combined in the proportions obtained in the usual process of milling and must not contain more than 6.0 per cent of crude fibre. (Adopted prior to 1928).

130. **Wheat Red Dog** is a by-product obtained in the usual commercial process of flour milling, consisting principally of aleurone with small quantities of wheat flour and fine wheat bran particles and must not contain more than 4.0 per cent of crude fibre. (Adopted prior to 1928).

131. **Wheat Low-Grade Feed Flour** is a by-product obtained in the usual commercial process of flour milling, consisting principally of wheat flour

with small quantities of aleurone and fine wheat bran particles and must not contain more than 1.5 per cent of crude fibre. (Adopted prior to 1928).

132. **Wheat Bran and Wheat Standard Middlings** consist of the two commodities as defined above, mixed in the proportions obtained in the usual process of commercial milling. (Adopted prior to 1928).

133. **Hard Wheat Mixed Feed** (mill-run wheat feed) consists of wheat bran and wheat flour middlings combined in the proportions obtained in the usual process of commercial milling. This product must not contain more than 9.5 per cent of crude fibre. (Adopted prior to 1928).

134. **Wheat Brown Shorts** (Wheat Red Shorts) consists mostly of the fine particles of wheat bran, wheat germ and very little of the fibrous offal obtained from the "tail of the mill". This product must be obtained in the usual commercial process of milling and must not contain more than 7.5 per cent of crude fibre. (Adopted prior to 1928).

135. **Wheat Gray Shorts** (Wheat Gray Middlings or Wheat Total Shorts) consists of the fine particles of the outer bran, the inner bran or bee-wing bran, the germ and the offal or fibrous materials obtained from the "tail of the mill". This product must be obtained in the usual process of commercial milling and must not contain more than 6.0 per cent of crude fibre. (Adopted prior to 1928).

136. **Wheat White Shorts or Wheat White Middlings** consists of a small portion of the fine wheat bran particles and the wheat germ and a large portion of the fibrous offal obtained from the "tail of the mill". This product must be obtained in the usual process of flour milling and must not contain more than 3.5 per cent of crude fibre. (Adopted prior to 1928).

137. **Wheat Mixed Feed** (mill-run wheat feed) consists of wheat bran and the gray or total shorts combined in the proportions obtained in the usual process of commercial milling. This product must not contain more than 8.5 per cent of crude fibre. (Adopted prior to 1928).

RECOGNIZED ENGLISH NAME AND ENGLISH SYNONYM, IF ANY	ARTICLE OR SUBSTANCE INDICATED BY THE NAME AND SYNONYM.
Capsicum; Red Pepper	The dried, ripe fruit of any species of Capsicum.
Cupric Sulphate; Copper Sulphate	Crystallized copper sulphate with impurities not exceeding commercial grade.
Ferric Oxide; Red Oxide of Iron	Ferric oxide with impurities not exceeding commercial grade.
Ferrous Sulphate	Crystallized ferrous sulphate with impurities not exceeding commercial grade.
Dextrose	A refined, crystallized sugar obtained chiefly by the hydrolysis of starch or or a starch-containing substance.
Glucose	A syrup obtained by the incomplete hydrolysis of starch or of a starch-containing substance.
Lactose; Milk Sugar	A sugar obtained from cow's milk.
Magnesium Sulphate; Epsom Salt	Magnesium sulphate with impurities not exceeding commercial grade.
Potassium Bitartrate; Cream of Tartar	Potassium bitartrate with impurities not exceeding commercial grade.
Potassium Nitrate; Saltpeter	Potassium nitrate with impurities not exceeding commercial grade.
Sodium Nitrate; Chili Saltpeter	Sodium nitrate with impurities not exceeding commercial grade.

Sodium Bicarbonate	Sodium bicarbonate with impurities not exceeding commercial grade.
Sodium Chloride; Common Salt	Sodium chloride with impurities not exceeding commercial grade.
Sodium Sulphate; Glauber's Salt	Sodium sulphate with impurities not exceeding commercial grade.
Sulphur	Sulphur with impurities not exceeding commercial grade.
Calcium Phosphate	Tricalcium salt of phosphoric acid with impurities not exceeding commercial grade.
Dicalcium Phosphate	Dicalcium salt of phosphoric acid with impurities not exceeding commercial grade.
Bone Ash	The ash obtained by burning bones with free access of air and containing 35-38% of P_2O_5.
Precipitated Calcium Carbonate; Precipitated Chalk	Precipitated calcium carbonate with impurities not exceeding commercial grade.
Rock Phosphate	Ground phosphate rock of commercial grade.
Phosphatic Limestone	Ground phosphate—containing limestone of commercial grade.
Limestone; Calcite	Ground calcium limestone of commercial grade.
Dolomitic Limestone; Dolomite	Ground calcium-magnesium limestone of commercial grade.
Shell	Ground shells of oysters or of other mollusks.
Oyster shell	Ground shells of oysters.

CHOPPING AND STORING ALFALFA HAY

UNIVERSITY OF ARIZONA LIBRARY

Operating electric motor-driven hay chopper under test at Purdue University dairy barn.

PURDUE UNIVERSITY
AGRICULTURAL EXPERIMENT STATION
LAFAYETTE, INDIANA

CHOPPING AND STORING ALFALFA HAY

T. E. Hienton and J. H. Hilton
Dep'ts. of Agricultural Engineering & Dairy Husbandry

Chopping hay before storing it in the barn has a number of advantages and, consequently, many questions are being asked about this method of handling the hay crop. In an attempt to answer some of these questions, a three-year study of the value of chopping alfalfa hay was made using the University dairy herd. This method of storing hay has been studied from the standpoint of (1) the moisture content, (2) saving in mow space, (3) ease of handling and feeding, (4) saving in hay and (5) the power requirement and cutting capacity of a 15-inch cutter.

Approximately 300 tons of alfalfa hay made from the first, second and third cuttings were chopped, stored and fed to cows and heifers in the University herd. The hay was cured in the field in the regular way and pitched directly from the truck or wagon into the cutter. On the average, it required two men to pitch the hay off the load and a third man to feed the cutter. The hay was cut with a 15-inch combination hay chopper and ensilage cutter operated with either a 5- or 7.5-horsepower electric motor.

Tests were conducted to determine the capacity of the cutter when operated by a 5- or 7.5-horsepower electric motor. The capacity, when driven by the 5-horsepower motor, was 2.55 tons per hour, and, with the 7.5-horsepower unit, 3.5 tons per hour with hay cut one inch in length. In these tests each motor carried an overload of approximately 10 per cent, so that the capacities would be slightly less under conditions where the motors were delivering their rated output. Motors under ordinary operating conditions should not be required to carry a constant overload. The smaller motor used 2.0 kilowatt-hours and the larger motor 2.2 kilowatt-hours per ton of hay chopped.

The following observations were made as a result of this study:

1. Hay containing 19 per cent moisture at the time of cutting and storing came through the storage period with a good green color. Hay containing 25 to 28 per cent moisture at time of storage mow-burned badly, and hay, containing 30 per cent moisture when stored, became badly charred. When this charred hay was fed to dairy cows, it produced digestive disturbances which caused a marked decrease in their daily milk production. There is also the danger of spontaneous combustion when hay containing a high moisture content is stored in barns.

Claims that chopped hay can be successfully stored when only partially cured are not based on facts and should never be made. Hay that is to be chopped and stored should be as dry or drier than long hay as it is normally stored in barns. The upper limit of moisture content to guard against spoilage of the hay is probably about 22 per cent with a one-inch cut as employed in these tests.

The hay should be distributed in the mow by adjusting the blower, and should not under any conditions be packed or tramped.

When equipment is available, chopped hay is more conveniently handled and is easier to feed than long hay.

2. Chopping alfalfa hay before storing will save approximately 55 per cent in mow space. When hay is chopped and blown into barns, care should be exercised to see that the mows are properly supported to take care of this additional weight.

3. In the University barn, the chopped hay proved to be more easily handled and also easier to feed than long hay. The hay was thrown from the mow into a silage cart and then fed from this cart. This method of feeding may not be practical in barns without concrete alleys and where the hay chute is some distance from the cows.

4. Most of the hay stored in this study was of good quality and no significant saving in feed was observed in these studies. There would undoubtedly be some saving in feed effected by chopping coarse hay.

5. It required slightly less time to store the hay by chopping than to store it in the regular way. The electric power cost at 4 cents per kilowatt-hour to operate the cutter was between 8 and 9 cents per ton. The fuel and oil costs in operating a 15-inch cutter with a tractor unit would be similar. The manufacturer's recommendation on the size of tractor required to drive this machine is 14 to 20 horse-power. If this larger size of power unit is used, it may be possible to secure a larger capacity than was obtained with either of the motors used in these tests.

Effect of Fertilizer on Yield of Potatoes
This circular gives the results of the inspection of 1,481 official samples of fertilizer.

UNIVERSITY OF ARIZONA LIBRARY

PURDUE UNIVERSITY
AGRICULTURAL EXPERIMENT STATION
LAFAYETTE, INDIANA

Otis Sidney Roberts, Inspector in the State Chemist Department for more than twenty-eight years including twenty-five years as Chief Inspector and one year as Acting State Chemist, died December 19, 1935. In the passing of Mr. Roberts the fertilizer, feed and seed industries, as well as the Agricultural interests of Indiana, have suffered a distinct loss of a loyal friend and an able worker.

This circular is a report of the inspection of commercial fertilizers for the year 1935. The inspectors visited every county in the state in both the spring and fall seasons and collected 1,481 official samples. This represents one sample for each 131 tons of fertilizer that were sold.

The Indiana Fertilizer Law is essentially a correct labeling act. It protects the honest and efficient manufacturer, dealer and agent as well as the consumer. In order to obtain maximum protection the consumer must read carefully and understand thoroughly the information on the state tag or label.

Refunds amounting to $346.64 were paid by 22 manufacturers on 61 shipments of fertilizers that were deficient in analysis.

Table 1 shows the average composition of common fertilizer materials as well as their comparative values per ton.

Table 3 gives the tonnages of the different analyses that were sold in largest amounts. The tonnage of 2-12-6 amounted to 40 per cent of all the fertilizer sold. More than 81 per cent of the total tonnage was confined to 33 analyses while less than 19 per cent was divided among the 119 other grades as reported by the manufacturers.

Table 5 shows the tonnage, retail value and pounds per ton of plant food. The cost per pound of plant food was slightly less than for 1934. The average content of plant food (N, P_2O_5 and K_2O) was 485 pounds per ton. The average analysis of all fertilizer sold was 2.1 per cent nitrogen, 13.0 per cent available phosphoric acid and 7.7 per cent water soluble potash.

Table 6 gives the classified tonnage sales of low and high analysis fertilizers for the last 21 years. Table 12 shows the standing of manufacturers as determined by the inspection for the year 1935. Table 13 shows the analysis of each of the 1,481 official samples collected.

COMMERCIAL FERTILIZERS

H. R. Kraybill, *State Chemist*
O. W. Ford, *Assistant Chemist* *O. S. Roberts, *Chief Inspector*
Assistant Chemists, L. E. Horat, M. H. Thornton
Assistant Inspectors, C. M. Cohee, J. W. Jackman

This circular presents the results of the inspection of commercial fertilizers sold in Indiana during the year 1935. It is estimated from tag sales that 194,944 tons of commercial fertilizer were sold. From the manufacturers' reports a tonnage of 190,067 is indicated. It is believed that the latter figure represents more nearly the actual tonnage sold. The difference between the two estimates is apparently due to the fact that the manufacturers increased their stocks of tags on hand during the year. The estimated tonnage for 1935 is about 30 per cent larger than for 1934.

Inspectors from the department visited every county in the state in both the spring and fall seasons and collected 1,481 official samples. This represents one sample for each 131 tons of fertilizer that were sold. Of these samples 1,399 were equal to or above the guarantee in value; 77 were within 10 per cent of the guaranteed value and 5 were 10 per cent or more below the guaranteed value. Seven of the 950 samples that contain nitrogen showed the presence of inferior nitrogen. The sources of nitrogen of these 7 samples were as follows: tobacco stems, dried manure and dried muck.

INDIANA FERTILIZER LAW

The Indiana Fertilizer Law is essentially a correct labeling act. The intent of the law is not to determine what type of fertilizer may be sold. High quality as well as low quality fertilizer may be sold provided it is correctly labeled. The law is designed to furnish the purchaser with a true statement of certain information on the state tag that will enable him to decide whether or not the fertilizer is the type that will meet his needs. The state tag shows the guaranteed percentages of total nitrogen, total or available phosphoric acid and water soluble potash. With this information available the purchaser should be able to judge whether the fertilizer offered for sale meets his requirements. *In order to do this the consumer must read carefully and understand thoroughly the information on the state tag.*

The Indiana Fertilizer Law protects the honest and efficient manufacturer, dealer and agent, as well as the consumer. Full co-operation on the part of the manufacturer, dealer, agent and consumer is necessary to accomplish the purpose of the law.

A copy of the full text of the law will be sent to persons making request for the same to the State Chemist, Purdue University Agricultural Experiment Station, Lafayette, Indiana.

REFUNDS

When deficiencies in analysis amounting to $1.00 or more per ton are found refunds are calculated and indicated on the report of analysis that is sent to the manufacturer and to the consumer. Refunds on mixed fertilizers are usually calculated when one ingredient is deficient to the extent of $1.00 or more per ton regardless of the excess in amounts of other ingredients. Nitrogen, phosphoric acid and potash play definite roles in crop production. An excess of the one ingredient will not necessarily compensate for a deficiency of another.

---

* Deceased December 19, 1935.

All refunds are required to be distributed to the consumer wherever possible, and receipts for the same must be filed with the State Chemist. In case there are no records as to the consumer the refunds may be turned over to a local charitable organization, but receipts for the same in either case must be filed with the State Chemist.

The payment of a refund by the manufacturer to the consumer does not remove the violation of the law, but it does indicate good intentions on the part of the manufacturer and shows his willingness to do what he can to correct the violation. However, the payment of the refund does not nullify the right of anyone in this state to call a deficiency of analysis to the attention of the prosecuting attorney.

Sixty-one of the 1,481 samples analyzed showed deficiencies in analysis sufficiently large to warrant the calculation of a refund. These errors are frequently due to carelessness in mixing or in attaching the tags. Manufacturers should guard against such errors. Refunds amounting to $346.64 were paid by 22 manufacturers on 61 shipments of deficient fertilizer in 1935.

MANUFACTURERS

The term "Commercial Fertilizer" is defined by law to include all materials used for manurial purposes except barnyard manure, marl, lime, wood ashes and plaster. Barnyard manure, sheep manure and muck when dried or processed in any way come under the provisions of the law. Before any commercial fertilizer is exposed or offered for sale or sold in the state it is necessary to register the fertilizer with the State Chemist and tag it properly with Indiana State Tags or Labels. Bulk shipments must be accompanied with sufficient labels to cover the total weight of the material.

Manufacturers should not ship fertilizer without having it properly tagged with Indiana State Tags. Experience has shown that when this is done it is difficult to avoid the sale of untagged fertilizer. The State Chemist has no authority to grant permission to a manufacturer to ship unlabeled fertilizer.

AGENTS, DEALERS AND DISTRIBUTORS

Agents should familiarize themselves with the provisions of the Indiana Fertilizer Law. Each package of fertilizer offered or exposed for sale or sold in Indiana must have attached to it the Indiana State Tag bearing the facsimile signature of the State Chemist (see reproduction, page 6). *In case you receive a car of untagged fertilizer, wire the manufacturer for tags and notify the State Chemist. Do not accept the shipment until proper tags are furnished.*

Since local agents are responsible for the fertilizer that they offer for sale they should deal only with those manufacturers who agree to assume full responsibility in cases where the fertilizer fails to meet the requirements of the law.

When inspection reports show that fertilizer in your possession is deficient enough so that a refund is calculated on it, withdraw it from sale at once and notify the State Chemist, giving the date and the amount withdrawn from sale.

CONSUMERS

The Indiana State Tag is your guarantee of the fertilizer that you purchase. Read the tag. Let the analysis on the state tag be your guide rather than the brand name. Refuse to accept any fertilizer which does not have the Indiana State Tag attached to each package.

When analysis of a fertilizer is desired, do not forward a sample, but notify the State Chemist, telling how much you have on hand and send in a copy of the official label which is attached to the fertilizer.

Purchase the type of fertilizer that will meet the plant food requirements of your crops. Consult Circular No. 162 of the Purdue University Agricultural Experiment Station, entitled "Fertilizers for Indiana Soils and Crops."

CAUTION

The consumer should remember that the presence of the Indiana state label with the facsimile signature of the State Chemist does not mean that the State Chemist recommends the fertilizer. Poor quality fertilizer may be sold legally, provided it is correctly labeled. The consumer should be guided by the analysis of the fertilizer.

MEANING OF ANALYSIS

Nitrogen.—In recent years water soluble forms of nitrogen have largely taken the place of the organic materials used years ago in mixed fertilizers. Today most of the nitrogen carrying mixed fertilizers have more than 80 per cent of their nitrogen content in water soluble form.

A few of the sources of water soluble forms of nitrogen are as follows: Nitrate of soda (Natural and synthetic), ammonium sulphate, cal-urea, cal-nitro, urea, cyanamid and calcium nitrate.

Since water soluble forms of nitrogen are considered as readily available for plant growth, if 60 per cent of the guaranteed nitrogen in a fertilizer is water soluble the nitrogen is regarded as of satisfactory quality.

If less than 60 per cent of the guaranteed nitrogen content is water soluble, the activity of the insoluble organic nitrogen is determined by the alkaline permanganate method. In this case, if the active water insoluble nitrogen is equal to or greater than the inactive, the nitrogen is classed as satisfactory. If less than half of the insoluble nitrogen is active, the nitrogen is classed as inferior. Manures, peat and garbage tankages that have not been acidulated will show an inferior quality of nitrogen. When these products are sold as manure and garbage tankage the manufacturer is not held responsible for the quality of the nitrogen.

Phosphoric Acid.—The phosphorus in superphosphate is linked up as chemical compounds with calcium, iron and aluminum. It may be present as mono-, di- or tricalcium phosphate.

As monocalcium phosphate $CaH_4(PO_4)_2$ it is water soluble and readily available to plants for growth.

As dicalcium phosphate $Ca_2H_2(PO_4)_2$ it is soluble in the soil solution and rendered available to plants for growth.

As tricalcium phosphate $Ca_3(PO_4)_2$ it is somewhat less available to plants.

As a complex tricalcium phosphate combined with fluorine and lime (raw rock phosphate) it is much less available to plants and becomes available only slowly in the soil.

The bulk of the fertilizer sold today contains mixtures of large amounts of mono- and dicalcium phosphate and some tricalcium phosphate. This is in contrast to the earlier years when most of the fertilizer used was bone where the phosphorus is present as tricalcium phosphate.

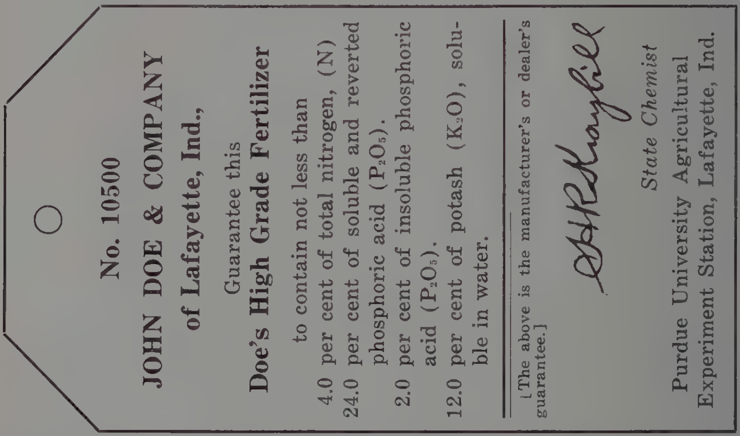
In acidulated goods the phosphorus is sold only on the basis of the available phosphoric acid (P_2O_5) content. The available is the sum of the soluble and reverted phosphoric acid (P_2O_5).

In bone and rock phosphate, when sold as such, the phosphorus is sold only on the basis of the total phosphoric acid (P_2O_5) content. It is only fair to state, however, that about 60 to 75 per cent of the total phosphoric acid (P_2O_5) content of bone is available by the neutral ammonium citrate method, while only from three to six per cent of the total phosphoric acid (P_2O_5) of rock phosphate is available by the same method.

Potash.—Potash, as the official label states, must be soluble in water, in which form it is considered directly available for plant use.

No difference in crop growth has been noted in the use of American, French or German potash. Muriate of potash (KCl) being the cheapest has largely supplanted other potash salts for general crops.

OFFICIAL STATE LABEL



No. 10500

JOHN DOE & COMPANY

of Lafayette, Ind.,

Guarantee this

Doe's High Grade Fertilizer

to contain not less than

4.0 per cent of total nitrogen, (N)

24.0 per cent of soluble and reverted phosphoric acid (P_2O_5).

2.0 per cent of insoluble phosphoric acid (P_2O_5).

12.0 per cent of potash (K_2O), soluble in water.

[The above is the manufacturer's or dealer's guarantee.]

H R Kraybill

State Chemist

Purdue University Agricultural Experiment Station, Lafayette, Ind.

The only label recognized under the law is that bearing the facsimile signature of the State Chemist. (See reproduction.) The label as issued is always printed and contains all the facts required by law; any alteration thereon constitutes a violation of the law.

Label No. 10500 guarantees that each 100 pounds of fertilizer will contain at least 4.0 pounds of total nitrogen (N), 24.0 pounds of soluble and reverted phosphoric acid (P_2O_5), 2.0 pounds of insoluble phosphoric acid (P_2O_5), and 12.0 pounds of water soluble potash (K_2O).

We hope that it will not again be necessary to file affidavits against agents for distributing unlabeled fertilizer. There can be no excuse for shipping unlabeled fertilizer. Agents receiving same should protect themselves by refusing to accept the car. Wire the manufacturer for official labels and write the State Chemist fully concerning the unlabeled shipment.

AVERAGE COMPOSITION OF FERTILIZER MATERIALS

Table 1 gives the average composition of some of the more common fertilizer materials and their comparative values per ton.

TABLE 1. Average Composition and Comparative Evaluation of the Common Fertilizing Materials

MATERIAL	Nitrogen Per Cents							Phosphoric Acid Per Cents			Water Soluble Potash Per Cent	*Comparative Value Per Ton
	Total	Water Soluble Organic	Water Soluble Ammonia	Water Soluble Nitrate	Water Insoluble Organic	Active Insoluble Organic	Inactive Insoluble Organic	Total	Insoluble	Available		
Sodium Nitrate	15.5			15.5								$31.00
Calcium Nitrate	14.0			14.0								28.00
Ammonium Sulphate	20.5		20.5									41.00

*Comparative values per ton calculated from table of comparative values for 1934.
Values appearing in the Inactive Insoluble Organic column in heavy type indicate an inferior source of nitrogen.

CLASSIFIED FERTILIZER SALES SINCE 1883

Table 2 illustrates the changes that have occurred in the types of fertilizers sold during the past 53 years.

TABLE 2. Classified Fertilizer Sales Since 1883 (From Tag Sales)

YEAR	Total Tons	Tons Nitrogen Salts	Tons Potash Salts	Tons Super-phosphate	Tons Bone	Tons Raw Phosphate Rock	Tons Phosphate Potash	Tons Ammoniated Super-phosphate	Tons Complete

*Largely Nitrate of Soda.
†Nitrate of Soda and Ammonium Sulphate.
‡Light Sales.

MANY GRADES UNNECESSARY

Table 3 shows the tonnage of fertilizer sold under the different grades of analyses. In 1935 more than 80 per cent of the tonnage was represented by 33 grades, while less than 20 per cent were distributed over 119 different analyses. Considerable saving in cost could be made by the manufacturer if the number of grades were reduced materially.

1935	1,481	1,275	1,399	77	5

PRICES USED IN SECURING COMPARATIVE VALUE OF FERTILIZERS

These values are not for the purpose of fixing the commercial value of mixed fertilizers, but are for comparative purposes only. They are for use in comparing the value of inspection samples with manufacturers' guarantees, and can be used advantageously by fertilizer purchasers in calculating the relative values of various brands offered for sale by different manufacturers.

For use in determining the comparative values of fertilizer inspected in 1936 the following prices have been adopted:

TABLE 9. Prices Used in Determining Comparative Values of Fertilizers

	Per pound cents	Per unit or per cent dollars
All fertilizers—		
Nitrogen (N)	10.0	2.00
Soluble and reverted phosphoric acid (P_2O_5)	5.0	1.00
Potash (K_2O) soluble in water	5.0	1.00
Mixed fertilizers containing nitrogen—		
Insoluble phosphoric acid (P_2O_5)	1.5	0.30
Precipitated bone—		
Available phosphoric acid (P_2O_5)	5.0	1.00
Insoluble phosphoric acid (P_2O_5)	1.5	0.30
Animal by-products, bone, tankage, etc—		
Total phosphoric acid (P_2O_5)	3.5	0.70
Basic Slag—		
Total phosphoric acid (P_2O_5)	4.5	0.90
Rock Phosphate (floats) and low grade slag—		
Total phosphoric acid (P_2O_5)	1.5	0.30
Mixed fertilizer, acid phosphate, etc., containing no nitrogen—		
Insoluble phosphoric acid	0.0	0.00

Table 10 gives the fertilizer tonnage for the spring and fall seasons as well as the total tonnage and estimated retail value for the year 1935.

TABLE 10. Fertilizer Tonnage and Estimated Retail Value, 1935

CLASS OF FERTILIZER	Spring 1935 Tons	Fall 1935 Tons	Total 1935 Tons	Estimated 1935 Retail Value
1. Superphosphate, 14% and less	94	488	582	$ 13,968.00*
2. Superphosphate, 16%	500	4,275	4,775	96,120.75
3. Superphosphate, 18-20%	3,594	11,438	15,032	247,923.28
4. Superphosphate, above 20%	344	813	1,157	57,387.20
5. Ammoniated Superphosphate (low)	31		31	372.00†
6. Ammoniated Superphosphate (medium)		94	94	1,222.00†
10. Superphosphate and Potash 14-19 units	313	813	1,126	28,037.40
10a. Superphosphate and Potash, above 20 units	14,888	7,344	22,232	699,641.04
11. Complete fertilizer (low)	188	469	657	15,590.61
12. Complete fertilizer (medium)	938	1,300	2,238	50,892.12
13. Complete fertilizer (high)	14,100	18,831	32,931	853,900.83
13a. Complete fertilizer, above 20 units	48,518	52,962	101,480	3,325,499.60
14. Steamed bone	219	1,281	1,500	46,305.00
15. Raw bone	250	1,028	1,278	46,647.00
16. Tankage		184	184	3,128.00*
21. Rock phosphate	500	156	656	13,120.00*
22. Nitrogen salts**	2,625	775	3,400	128,418.00
‡Cyanamid	25	325	350	
‡Nitrate of Soda	850	400	1,250	
‡Ammonium Sulphate	1,750	50	1,800	
23. Potash salts**	4,450	100	4,550	170,943.50
‡Muriate of Potash 0-0-50	4,100	50	4,150	
‡Muriate of Potash 0-0-60	250	50	300	
‡Sulphate of Potash	100		100	
31. Miscellaneous (peat, dried manure, dried blood, garbage, tankage, etc.)	869	172	1,041	40,078.50
Total	92,421	102,523	194,944	$5,839,194.83

**Tonnage in these classes estimated on the basis of 200-pound bags or 10 bags per ton. All other classes estimated on basis of 125-pound bags or 16 bags per ton. Cyanamid estimated on the basis of 100-pound bags or 20 bags per ton.

*Calculated from 1934 retail price.

†Calculated from the comparative values used in 1935.

‡Not included in totals.

*Tobacco stems.
†Dried manure.
‡Dried muck.

These are inferior sources of nitrogen and the manufacturer is not responsible when they are sold unmixed with other materials.

DEFINITION OF TERMS AND INTERPRETATION OF RESULTS ON FERTILIZERS AND LIMING MATERIALS ADOPTED BY THE ASSOCIATION OF OFFICIAL AGRICULTURAL CHEMISTS

NITROGEN

Acidulated fish tankage, acidulated fish scrap, is the rendered product derived from fish and treated with sulfuric acid.

Activated sewage products are made from sewage freed from grit and coarse solids and aerated after being inoculated with microorganisms. The resulting flocculated organic matter is withdrawn from the tanks, filtered with or without the aid of coagulants, dried, ground, and screened.

Charred peat is peat artificially dried at a temperature that causes partial decomposition.

Cyanamid is a commercial product composed chiefly of calcium cyanamid ($CaCN_2$), and it shall contain not less than twenty-one per cent (21%) of nitrogen.

Cyanamid and urea nitrogen is synthetic non-proteid organic nitrogen.

Crude, inert, or slow-acting nitrogenous materials are unprocessed organic substances relatively high in nitrogen but having a very low value as plant food and showing a low activity by both the alkaline and neutral permanganate methods (below fifty per cent [50%] and eighty per cent [80%] respectively).

Dried blood is the collected blood of slaughtered animals, dried and ground and containing not less than twelve per cent (12%) of nitrogen in organic forms.

Fish tankage, fish scrap, dry ground fish, fish meal fertilizer grade is the dried ground product derived from rendered or unrendered fish.

Garbage tankage is the rendered, dried and ground product derived from waste household food materials.

Hoof and horn meal is a product resulting from the processing, drying, and grinding of hoofs and horns.

Nitrate of soda is a commercial sodium nitrate containing not less than fifteen per cent (15%) of nitrogen, chiefly as sodium nitrate.

Peat is partly decayed vegetable matter of natural occurrence. It is composed chiefly of organic matter which contains some nitrogen of low activity.

Process tankages are products made under steam pressure from crude inert nitrogenous materials, with or without the use of acids, for the purpose of increasing the activity of the nitrogen. These products shall be called "Process Tankages" with or without further qualification. The water-insoluble nitrogen in these products shall test at least fifty per cent (50%) active by the alkaline, or eighty per cent (80%) by the neutral permanganate method.

Sheep manure-wool waste is the by-product from wool-carding establishments consisting chiefly of sheep manure, seeds, and wool fiber.

Sulfate of ammonia is a commercial product composed chiefly of ammonium sulphate. It shall contain not less than twenty and five-tenths per cent (20.5%) of nitrogen.

The term *tankage* (without qualification) shall be restricted to meat and bone tankage derived from the rendered, dried, and ground by-products from the slaughter of animals, or from carcasses of animals that have died otherwise than by slaughter.

PHOSPHORIC ACID

The term *phosphoric acid* designates (P_2O_5).

Ammoniated superphosphate is a product containing superphosphate and/or dissolved bone and nitrogenous compounds, but without the addition of potash.

Available phosphoric acid is the sum of the water-soluble and the citrate-soluble phosphoric acid.

"Basic" lime phosphate (lime based superphosphate) is a superphosphate to which liming materials have been added in a quantity at least six per cent (6%) calcium carbonate equivalents in excess of the quantity required to convert all water-soluble phosphate to the citrate-soluble form.

Basic phosphate slag is a by-product in the manufacture of steel from phosphatic iron ores. The product shall be finely ground and shall contain no admixture of materials other than what results in the original process of manufacture. It shall contain not less than twelve per cent (12%) of total phosphoric acid (P_2O_5), not less than eighty per cent (20%) of which shall be soluble in two per cent (2%) citric acid solution according to the Wagner method of analysis. Any other phosphate slag not conforming to this definition shall be designated low grade.

Citrate-soluble ("reverted") phosphoric acid is that part of the total phosphoric acid in a fertilizer that is insoluble in water but soluble in a solution of citrate of ammonia according to the method adopted by the A. O. A. C.

Definition of Products Secured by Heating Calcium Phosphate with Alkali Salts Containing Potash. These products are not potassium phosphate. They may be called non-acid phosphates with potash.

Dicalcium phosphate is a manufactured product consisting chiefly of a dicalcic salt of phosphoric acid.

Dissolved bone is defined as a ground bone or bone meal that has been treated with sulfuric acid.

Ground raw bone is a product resulting from drying and grinding animal bones that have not been previously steamed under pressure.

Ground steamed bone is a product resulting from grinding animal bones that have been previously steamed under pressure.

Mono-ammonium phosphate (fertilizer grade) is a commercial salt made by combining phosphoric acid with ammonia. It shall contain not less than ten per cent (10%) of nitrogen and not less than forty-six per cent (46%) of available phosphoric acid.

Phosphate rock is a natural rock containing one or more calcium phosphate minerals of sufficient purity and quantity as to permits its use, either directly or after concentration, in the manufacture of commercial products.

Precipitated bone phosphate is a by-product from the manufacture of glue from bones and is obtained by neutralizing the hydrochloric acid solution of processed bone with calcium hydroxide. The phosphoric acid is chiefly present as dicalcium phosphate.

Precipitated phosphate is a product consisting mainly of dicalcium phosphate obtained by neutralizing with calcium hydroxide the acid solution of either phosphate rock or processed bone.

Soft phosphate with colloidal clay is a very finely divided low-analysis by-product from mining Florida rock phosphate by a hydraulic process in which the colloidal materials settle at points in artificial ponds and basins farthest from the washer, and is later removed after the natural evaporation of the water.

Superphosphate is the product resulting from mixing rock phosphate and sulfuric acid and/or phosphoric acid. The grade should always be used as a prefix to the name. Example: 16% Superphosphate.

It is recommended that the use of the term "Acid Phosphate" be discontinued.

Uniformity in Use of Terms "Phosphoric Acid" and "Potash." As the terms phosphoric acid and potash are used universally in guaranteeing and in reporting the analyses of fertilizers, it is recommended that the same terms also be used in reporting and discussing the results of analyses of related materials.

POTASH

The term *potash* designates potassium oxide (K_2O).

Kainit is a potash salt containing potassium and sodium chlorides and sometimes sulfate of magnesia with not less than twelve per cent (12%) of potash (K_2O).

Leached wood ashes are defined as ashes resulting from burning unleached wood, but as having had part of their plant food removed by artificial means or by exposure to rains, snows, or other solvent.

Manure salts shall be be understood to mean potash salts containing high percentages of chloride and from twenty per cent (20%) to thirty per cent (30%) of potash (K_2O). The term double manure salts should be discontinued.

Muriate of potash is a potash salt containing not less than forty-eight per cent (48%) of potash (K_2O) chiefly as chlorides.

Nitrate of potash is a salt containing not less than twelve per cent (12%) of nitrogen and forty-four per cent (44%) of potash (K_2O).

Sulfate of potash-magnesia is a potash salt containing not less than twenty-five per cent (25%) of potash (K_2O), nor less than twenty-five per cent (25%) of sulfate of magnesia, and not more than two and five-tenths per cent (2.5%) of chlorine.

Sulfate of potash is a potash salt containing not less than forty-eight per cent (48%) of potash (K_2O) chiefly as sulfate, and not more than two and one-half per cent (2.5%) of chlorine.

Unleached wood ashes are ashes that result from burning unleached wood, that have had no part of their plant food removed and that contain four per cent (4%) or more of water-soluble potash (K_2O).

Ashes from leached wood are defined as unleached ashes resulting from burning wood that has been exposed to or digested in water or other liquid solvent, as in the extraction of dyes, so that a part of the plant food has been dissolved and removed.

LIMING MATERIALS

Agricultural liming material is any substance that contains calcium and magnesium in condition and quantity suitable for use in neutralizing soil acidity.

Air-slaked lime is the product obtained by exposing quicklime or hydrated lime to the atmosphere until partially carbonated.

Ground limestone is the product obtained by grinding either calcareous or dolomitic limestone. Not less than seventy-five per cent (75%) shall pass a 100-mesh sieve. It shall contain calcium and magnesium carbonate equivalent to not less than ninety per cent (90%) of calcium carbonate.

Ground shell marl is the product obtained by grinding natural deposits of shell marl. Not less than seventy-five per cent (75%) shall pass a 100-mesh sieve. It shall contain calcium and magnesium carbonates equivalent to not less than eighty per cent (80%) of calcium carbonate.

High-calcic products are materials in which 90 per cent or more of the total calcium and magnesium oxide content consists of calcium oxide.

Hydrated or slaked lime is the product obtained by treating quicklime with sufficient water or steam to combine with its oxides.

Interpretation of the Word "Lime" as applied to Fertilizers. The term "lime" shall not be used in the registration, labeling, or guaranteeing of fertilizers or fertilizer materials unless the lime is in a form to neutralize soil acidity such as the oxide, hydroxide or carbonate, or equivalent magnesia compounds.

The word *lime* when applied to liming materials means either calcium oxide or calcium and magnesium oxides.

Quicklime, burned lime, caustic lime, lump lime, unslaked lime, are liming materials that have a high content of calcium oxide (with magnesium oxide) produced by heating suitable carbonates until substantially all of the carbon dioxide has been eliminated.

Waste lime, by-product lime, is any industrial waste or by-product containing calcium or calcium and magnesium in forms that will neutralize acids. It may be designated by the prefixation of the name of the industry or process by which it is produced, i. e., gas-house lime, tanners' lime, acetylene lime-waste, lime-kiln ashes, calcium silicate, etc.

FORMULA, GRADE, ANALYSIS, ETC.

The word *analysis,* as applied to fertilizers, shall designate the percentage composition of the product expressed in terms of nitrogen or ammonia, phosphoric acid, and potash in their various forms.

The term *fertilizer formula* shall be interpreted as expressing the quantity and grade of the crude stock materials used in making a fertilizer mixture. For example: 800 pounds of 16 per cent superphosphate, 800 pounds of 9-20 tankage, and 400 pounds of sulfate of potash-magnesia.

The grade of a fertilizer shall represent the minimum guarantee of its plant food expressed in terms of nitrogen, available phosphoric acid, and water-soluble potash.

The statement of guarantees of mixed fertilizers shall be given in whole numbers.

The *order of terms* in mixed fertilizers shall be nitrogen first, phosphoric acid second, and potash third.

BRAND AND BRAND NAME

A brand is a term, design, or trade mark used in connection with one or several grades of fertilizers.

A brand name is a specific designation applied to an individual fertilizer.

Interpretation of Brand Name to include the analysis or grade of fertilizer. The committee recommends and urges the practice of including the analysis or grade of fertilizer with the brand name, both by the manufacturer on sacks and in printed literature and by the control official in his reports and publications.

Significance of the Name of a Material used as the brand name or part of the brand name of a mixed fertilizer. When the name of a material is used as a part of the brand name of a mixed fertilizer, as for example blood, bone or fish, the nitrogen or phosphoric acid shall be derived from or supplied entirely by the material named. When the name of a material is used as a brand or as part of a brand and the nitrogen and phosphoric acid is not supplied by the material named, the word "brand" shall follow the name of the material. Example: "Fish Brand Fertilizer."

MISCELLANEOUS

A unit of plant food is twenty (20) pounds, or one per cent (1%) of a ton.

Net Weights. The weights appearing on packages of fertilizer, agricultural lime, and liming material shall always mean net weights.

Maximum Amount of Chlorine Permissible in Fertilizers in Which the Potash Is Claimed as Sulfate. The chlorine in mixed fertilizers in which the potash is claimed as sulfate shall not exceed five-tenths of one per cent (0.5%) more than what is called for in the minimum potash content based on the definition for sulfate of potash as formulated by the committee. Calculate as follows: 0.05 times the percentage of potash found plus 0.5.

Dried pulverized or shredded manures shall be only what the name indicates, and not mixtures of manures and other materials.

The term *finely ground* in the definition of basic phosphate slag shall refer to actual size of particles as determined by the use of standard sieves, as follows: Seventy per cent (70%) or more should pass a 100-mesh sieve, and ninety per cent (90%) or more should pass a 50-mesh sieve.

Gypsum, land plaster, or crude calcium sulfate, are products consisting chiefly of calcium sulfate. They may contain twenty per cent (20%) of combined water. (They do not neutralize acid soils.)

As the terms *phosphoric acid* and *potash* are used universally in guaranteeing and in reporting the analyses of fertilizers, it is recommended that the same terms also be used in reporting and discussing the results of analyses of related materials.

The water-soluble or available *manganese* in fertilizers shall be expressed as manganese (Mn).

The term *manganese sulfate,* when connoting an ingredient of a mixed fertilizer, shall designate anhydrous manganous surfate ($MnSO_4$).

High-magnesic products are materials in which more than 10 per cent of the total calcium and magnesium oxide content consists of magnesium oxide.

Table 13 gives a detailed analysis of the individual official inspections for the year 1935.

TABLE 13. Report of Inspection of Fertilizer Collected in 1935

Where 60.0 per cent or more of the total nitrogen guaranteed was found to be water soluble, the active and inactive insoluble organic nitrogen was not determined.

Percentages appearing in bold type in the "Inactive water insoluble organic" column denote inferior nitrogen.

Where 60.0 per cent or more of the total nitrogen guaranteed was found to be water soluble the active and inactive insoluble organic nitrogen was not determined.

Percentages appearing in bold type in the "Inactive water insoluble organic" column denote inferior nitrogen.

Where 60.0 per cent or more of the total nitrogen guaranteed was found to be water soluble, the active and inactive insoluble organic nitrogen was not determined.

Percentages appearing in bold type in the "Inactive water insoluble organic" column denote inferior nitrogen.

[137] Not tagged. Labels furnished.

[138] Sample received in the spring.

[139] Not tagged. Labels furnished.

[140] Refund $3.60.

[141] Refund $7.50. Sample to manufacturer. Used on own farm.

INSECT PESTS OF MUCK CROPS

GEORGE E. GOULD, Department of Entomology

Muck crops of Northern Indiana are attacked by a number of serious insect pests, most of which can be readily controlled by the application of proper remedial measures. Determination of the proper methods of control requires some knowledge of the life history and habits of these insects and their type of mouthparts. In this bulletin the latest developments in control of the principal muck crop pests are discussed.

Cultural and sanitary practices about the farm are important in the reduction of insect populations and often check pests before they multiply and become widespread. Crop rotation, summer fallowing, clean cultivation, early fall plowing, and the destruction of old crop remnants are often determining factors in maintaining insect populations at a minimum. Weeds in cultivated fields, in fence rows and in adjoining pasture or waste land, are ideal breeding grounds for many pests. Under normal conditions many of our common insects are held in check by weather and by parasites and predators. Among recent investigations the development of varieties that are resistant or tolerant of insect attack offers some promise in the economical production of certain muck crops, which heretofore have been treated with insecticides with only partial success.

Control through the use of insecticides is based on a knowledge of insect structures, especially of the mouthparts. In this respect insects are generally divided into two groups, according to whether they have jaws or mandibles for chewing portions of plant tissue, or whether they have a beak for sucking out the plant juices. Chewing insects are usually controlled by the use of stomach poisons, such as arsenate of lead, calcium arsenate and Paris green, which are applied to the plant surfaces and are eaten with the food. Sucking insects are controlled by the use of contact poisons, such as nicotine, pyrethrum and derris extracts, oils and soaps, which kill by coming in contact with the body of the insect. Injury by chewing insects, of which beetles, grasshoppers, caterpillars and grubs are examples, is recognized by defoliation of leaves, by small holes in the leaves, by tunnelling or mining of leaves, stems or roots, or by skeletonizing of leaves. Injury by sucking insects, of which plant lice, plant bugs and leafhoppers are examples, is more difficult to recognize but is usually noticeable by the curling of leaves, the malformation of terminal plant growth, wilting of the plant, failure to make growth, and often by the yellowing of affected parts.

Successful insect control depends largely upon the proper treatment at the proper time. A small, localized infestation is much cheaper and more easily controlled than when the pest is widespread over the field. Suitable spraying and dusting equipment is essential, if insecticides are to be economically and effectively applied. Every muck farm with two or more acres of mint and vegetables should have either a power sprayer or a power or traction duster. When a grower has over a hundred acres in crops that may need treatment, at least two outfits should be available. Most growers prefer spraying and in normal seasons have no difficulty in pulling a full sprayer over their fields, especially if the wheels are equipped with extension rims. In purchasing a sprayer a grower should obtain one capable of maintaining at least 200 pounds pressure and equipped with three nozzles per row. Dusters because of their lighter weight and lower cost, are preferred by some. Most traction dusters are capable of covering four rows with two adjustable nozzles per row. Every farm should also have either a hand duster or sprayer for crops grown on a small scale, for spot treatment of isolated, infested plants, or for plants in seed beds. All spraying and dusting equipment should be equipped with adjustable, angle nozzles, which are so essential in properly applying materials to the undersides of the foliage.

A recent complicating problem in the chemical control of insects is the Federal regulation on the amount of spray residue on marketed vegetables, which is recognized in the insecticidal recommendations hereafter suggested.

INSECT PESTS OF CABBAGE AND RELATED CROPS

Cabbage, and to a lesser degree, cauliflower, broccoli, Brussels sprouts, kohlrabi, Chinese cabbage, kale, turnips, and radishes are important crops on muck soils and are severely damaged by a number of pests. These include several kinds of cabbage worms, plant lice, cabbage maggot, cutworm, and flea beetles.

Cabbage Worms.—Four different caterpillars feed on cabbage and of these the imported cabbage worm is perhaps the commonest and most important. The common cabbage worm (Fig. 2) which is the larval stage of a white butterfly, is velvety green in color and about an inch long. It feeds on the upper leaves and about the cabbage head, often eating into the head itself. This insect breeds throughout the summer and is more destructive to the later crops. Hibernation takes place as pupae under old cabbage plant debris.

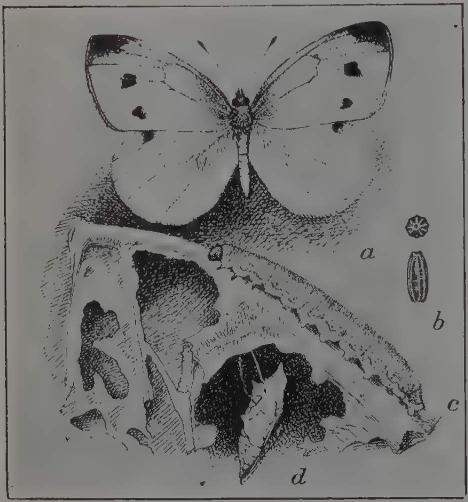

Fig. 2. The common green cabbage worm is the larval stage of the familiar white butterfly. (After Chittenden).

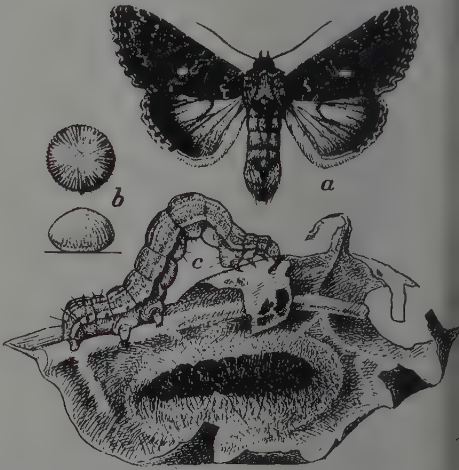

Fig. 3. The cabbage looper is the larva of a brownish moth. (After Chittenden).

The Cabbage Looper (Fig. 3) is quite destructive certain seasons but is normally held in check by parasitic insects and diseases. This pest, which is the larval stage of a brown moth, is light green in color and one and a half or more inches in length. It is readily distinguished from the common cabbage worm by its looping movement similar to a "measuring worm" and by its habit of feeding on the lower surfaces of the older or lower leaves. Damage usually occurs from this pest in late summer and early fall.

The other two worms, *the caterpillar of the diamond-back moth,* a small green worm, and *the zebra caterpillar,* a striped yellow and black worm, are pests of minor importance. They are controlled by the same applications used for the other cabbage worms.

Control.—Cabbage worms and loopers are difficult to kill and so it is advisable to use strong poisons early in the seasons. Applications should be made about 10 days after setting plants in the field and again 10 days later. Occasionally it may be necessary to treat the plants in the seed bed or to dip them in the process of transplanting. For these early applications the cheaper metallic poisons, such as arsenate of lead, can be used, but after the cabbage commences to head, only non-poisonous materials, such as derris, cube and pyrethrum, are recommended. Dusts usually give better control, as sprays adhere poorly to cabbage foliage.

Three dust mixtures, Paris green 1 pound mixed with 9 pounds of hydrated lime; arsenate of lead 1 pound with 5 pounds of lime; or cryolite 1 pound with 2 pounds of clay or talc and 1 pound dusting sulphur, will give good results when dusted on both surfaces of the foliage, especially if loopers are present. As a spray, 2 pounds of arsenate of lead and 2 to 3 pounds of good laundry soap are used in 50 gallons of water.

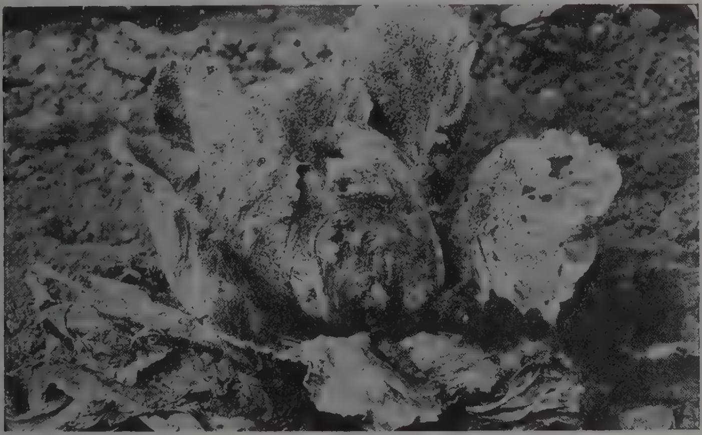

Fig. 4. Cabbage is often infested with gray, mealy lice or aphids. (After Davis).

Normally two applications early in the season will check cabbage worms but if late treatments are necessary, the non-poisonous derris powder should be used. Derris powder is mixed with powdered clay, flour or other inert dust to contain ½ per cent active ingredients and is used dry as a dust. In experimental tests derris powder containing 5 per cent active ingredients used in water at a rate of 2 pounds in 50 gallons and with a spreader added gave results even better than the dust. Derris powder and the ready-mixed derris dust, which is sometimes called rotenone dust, are rather high in cost but do give exceptionally good control of the worms and are especially useful when treatment is necessary shortly before the crop is harvested.

Cabbage Louse.—Cabbage lice or aphids are often a serious problem in the production of a cabbage crop. These small, waxy insects appear soon after the plants are set in the field and with favorable climatic conditions breed up in large numbers (Fig. 4) and kill the plants. Turnip lice, which prefer turnips and mustard, and spinach lice are also common on various cabbage crops. These insects have a short life cycle and can increase to enormous numbers if allowed to go unchecked. The first infested plants must be thoroughly sprayed or burned if the infestation is to be stopped. Parasites are important in keeping lice under control in warm weather, but in the cooler seasons the lice breed faster than their enemies.

Control.—In order to control plant lice infested plants must be thoroughly sprayed with a solution of 2/3 pint of 40 per cent nicotine sulphate in 50 gallons of water in which 2 or 3 pounds of good laundry soap has been dissolved. All lice should actually be hit with the spray. For dusting, 5 pounds of 40 per cent nicotine sulphate is mixed with 95 pounds of hydrated lime. This mixture must be prepared fresh and should be applied on quiet days when the temperature is above 65° or 70° F.

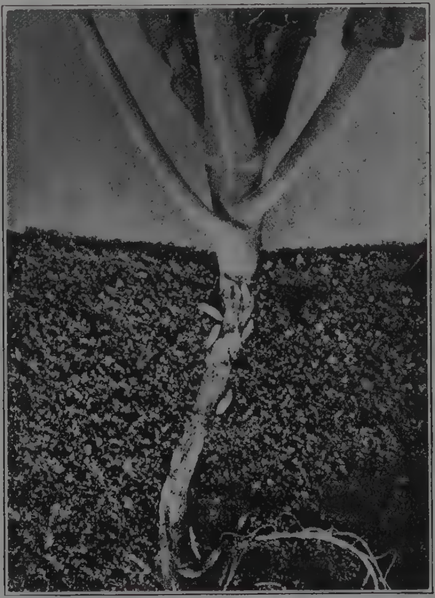

Fig. 5. The roots of cabbage, radishes, and onions are frequently attacked by white, legless maggots.

Cabbage Maggot.—Cabbage maggots are small, white, legless worms, the larval stage of a fly, which feed on the roots of cabbage (Fig. 5), radish and related crops, especially in cool, wet seasons. Plants may be attacked in the seed bed or after being transplanted in the field. The feeding on the roots cuts off the food supply and causes wilting and in severe infestations the death of the plant. This pest winters in a brown puparium in the soil and the adult flies emerge in early spring. Eggs are laid in the soil near the plant.

Control.—The maggots can be controlled by the use of a corrosive sublimate solution applied about the plants. This solution is made by dissolving 1 ounce of corrosive sublimate (bichloride of mercury) in a small quantity of hot water in a glass, earthenware or wooden receptacle and then adding sufficient water to make 10 gallons. This material is poisonous and will corrode all metals. The solution is applied around each plant so that the soil is thoroughly wet. The first application should be made in early May as soon as the eggs become abundant. A second application a week later may be necessary if the weather continues wet and cold. The solution can be applied with a sprinkling can with the sprinkler removed, or from a barrel mounted on a wagon, using two or more leads of hose. A gallon of solution should treat 75 small plants.

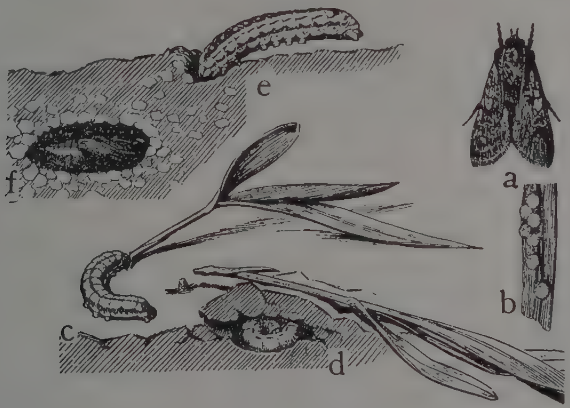

Fig. 6. Cutworms are common pests of muck crops growing in the spring. a, moth; b, eggs (enlarged); c, d, and e, larvae; f, pupa. (U. S. D. A.)

Cutworms.—Cutworms (Fig. 6) of many varieties are found in muck fields attacking practically all crops grown. Cabbage, especially when first transplanted, is subject to severe loss from several species of cutworms, some of which cut off the plants at the ground surface and some of which feed underground. The adult stages of these insects are the common dull, brownish moths that are attracted to lights during early summer. The female moth lays her eggs usually on grasses and the caterpillars are about half grown by fall. After spending the winter sheltered by weeds, grass, and other debris, the cutworms become active in the spring and feed voraciously on whatever green food they can find. These pests are nocturnal in habits and can cut off many plants during a night. Grassy fields and cold, damp springs are favorable for cutworm abundance.

Control.—In small garden areas cutworms can be trapped under boards placed on the ground. The cutworms collecting under the boards are removed and destroyed daily. Damage to transplanted plants, such as cabbage and tomatoes, can be prevented by loosely wrapping them with a three-inch band of paper so that about half of the paper is below the surface. The most effective control measure in the farm garden or in large fields is, of course, the use of a poison bran bait. This bait is made by mixing dry 1 pound of Paris green in 25 pounds of bran, and then adding 2 quarts of cheap, strong molasses and sufficient water (about 2 gallons) to make the mixture slightly damp. This mixture should be scattered about sunset over the infested field either previous to planting the crop or about the plants as they come up. The rate of application should not be more than 15 pounds to the acre.

INSECT PESTS OF CELERY

Tarnished Plant Bug.—This insect is perhaps the commonest pest found in the vegetable garden and in addition feeds on many weeds, greenhouse plants and some fruit trees. The adults of this insect are mottled brown in color. The young bugs resemble the mature form, except they are smaller, wings are absent and they have a greenish tint. All stages of the insect are quite active and disappear quickly when disturbed. The tarnished plant bug is a sucking insect and feeds on celery, potatoes, tomatoes, beans, Chinese cabbage, turnips, cabbage and cauliflower. Its abundance on cultivated crops is correlated closely with weeds in the field, along the fence rows or in adjoining pasture or idle land. A definite migration from white top and related composite plants, takes place in late July and August as these weeds dry up and die.

Fig. 7. Weeds growing in and around fields of celery and potatoes are breeding places for the tarnished plant bug.

Damage to celery is particularly noticeable at the joints where the bugs prefer to feed. These feeding punctures cause some injury and often allow bacteria and other disease organisms to enter. Such celery has to be trimmed and often only the hearts are marketable. In the case of potatoes the damage is caused by puncturing the growing tips, which subsequently wilt and die. Injury is more severe to crops growing or maturing in August. There are three or four generations of these insects each season in Northern Indiana.

Control.—This pest is exceedingly difficult to control with insecticides because it is active and contact insecticides have little effect even on the younger

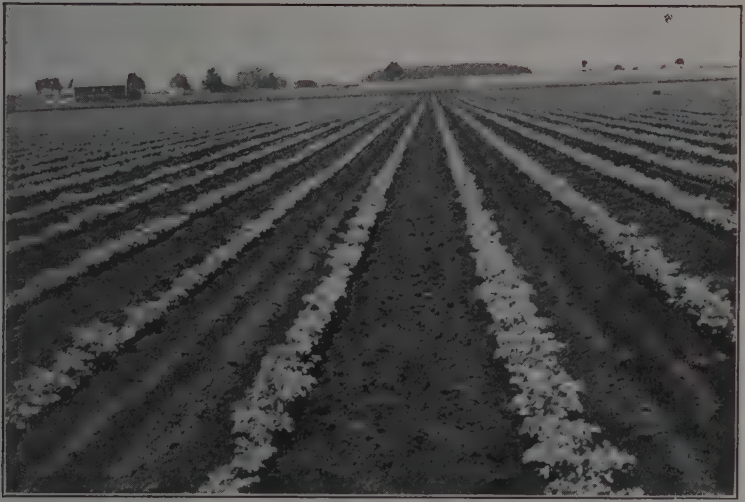

Fig. 8. Clean cultivation of muck crops helps to eliminate many insect pests, including the tarnished plant bug.

stages. Of greatest importance in control is the elimination of all weeds in the fields (Figs. 7 and 8) and also the elimination, before blossom time, of weeds growing in adjoining land. The commonly used Bordeaux spray and copper-lime dust on celery for disease control and on potatoes for disease and leafhopper control are of some value as repellents. In New York State growers find that dusting with hydrated lime lessens the injury, while dusting sulphur (300 mesh) when used alone or combined with lime in either a dust or spray gave good control on both early and late celery at a reasonable cost. An average of four or five applications of 25 to 35 pounds per acre of dust and 100 gallons of a 12-12-50 sulphur-lime-water spray are necessary when the bugs are numerous. A mixture of 1 pound of fresh, finely ground pyrethrum powder and 3 pounds dusting sulphur may be used when the young are present in large numbers.

Certain celery varieties are more resistant or tolerant to plant bug injury than others. While these resistant strains are of the green celery type, they offer some hope that the plant breeders can develop immunity in the more desirable yellow types.

Minor Pests of Celery.—Several kinds of leafhoppers, plant bugs and plant lice occasionally are found on celery but are rarely of sufficient importance to justify control measures. The celery looper and the celery caterpillar are sometimes found on celery but seldom in large numbers. In some sections of the state, especially where southern celery has been shipped in during the winter and spring months, the celery leaf tier has appeared in destructive numbers. This insect also works on various plants in the greenhouse and it is possible for greenhouse-grown celery plants to become infested. In Florida the control of this pest is by the use of fresh pyrethrum powder, applied twice at a 30-minute interval.

INSECT PESTS OF CUCUMBERS, MELONS AND SQUASH

Cucumber Beetles.—The most destructive pests on all cucurbit crops are the striped and the spotted cucumber beetles, which not only destroy the small plants as they first come through the ground, but also feed on the foliage and blossoms of mature plants and carry the wilt disease organism from plant to plant. The striped cucumber beetle, which is yellow with three black stripes (Fig. 9) is usually the common variety observed while the 12-spotted cucumber beetle, which is slightly larger in size and with 12 black spots on the wings, feeds on a number of different crops and is sometimes conspicuous attacking cucurbits. The exact hibernation habits of the spotted beetle are not known but they appear in late May or early June and possibly have two generations in Northern Indiana. The striped cucumber beetles winter on southern slopes in woods under leaves and loose soil and especially in lowlands. They come out early in the spring and feed on the pollen of many early-blooming trees and plants. As cucurbit crops come up, these beetles migrate into the fields in large numbers and often destroy all of the small seedling plants. There are two and perhaps three generations of the striped form each year with the fall individuals feeding on the pollen of wild flowering plants. In addition the slender white larvae or worms, hatching from the eggs laid in the soil, feed on the roots of cucurbits.

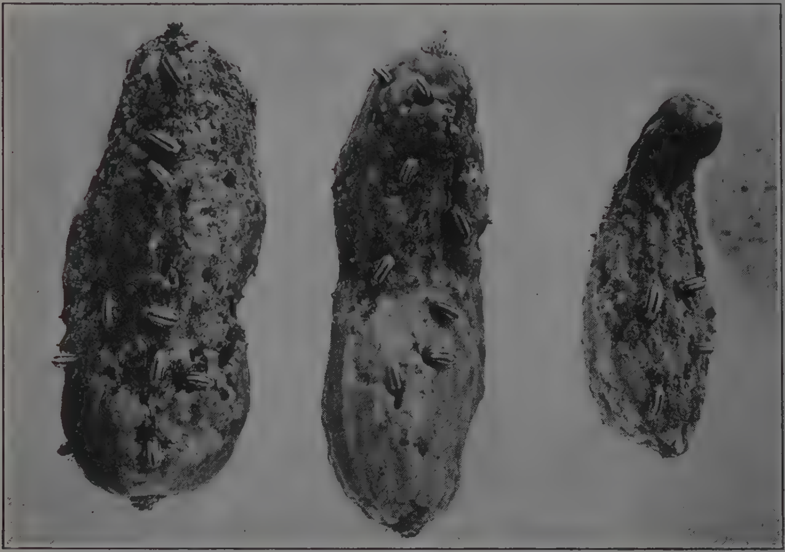

Fig. 9. The striped cucumber beetle destroys cucumber by its feeding and by spreading cucurbit wilt.

Even more destructive than the feeding of the beetles or the larvae is the wilt disease they spread among cucumbers and melons. The only carrier of this disease from plant to plant and through the winter is this beetle. A single bite on a healthy plant is sufficient to infect it although the symptoms of the disease do not show up for several weeks. The first evidence of the disease is the wilting of the vines during the heat of the day. After alternately wilting and recovering for several days, the leaves turn brown and the plant dies. Death of plants from wilt starts about the time of the first harvest and continues throughout the season. It is estimated that the yield of pickles in Northern Indiana is cut at least in half by this disease. The only known control of wilt is to completely control the striped cucumber beetle.

Control.—Cucumber beetles are rather difficult to control as they are repelled from plants covered with lime or arsenicals. The most effective mixture consists of 1 pound of calcium arsenate in 9 pounds of gypsum or land plaster (300 mesh grade). While this mixture is somewhat repellent, a thorough but not necessarily heavy coating over the plants at all times gives good results. The first application should be made as the plants come through the ground and repeated at four to seven day intervals, depending upon the plant growth and rainfall. A total of six to nine applications are necessary in the normal season. The material can be applied with a small duster or, if such equipment is not available, by shaking in a burlap sack or a bucket with small holes in the bottom. Hydrated lime or mixtures containing lime, such as Bordeaux spray or copper-lime dust are not advised on cucurbits as they often cause severe burning and stunting. In recent experiments at this station preliminary tests with certain insoluble copper compounds in both spray and dust forms gave excellent control of the beetles and wilt but the results of a single season's test would not warrant recommendations.

Melon Louse.—Plant lice or aphids are frequently serious pests on cucurbit crops. They breed very rapidly, living on the undersides of the leaves and causing the leaves to curl.

Control.—Successful control using the nicotine sulphate as for cabbage lice is accomplished only by thoroughly applying the insecticide to the under surfaces of the leaves. It is often possible to prevent an infestation from spreading by roguing out and burying the first hills infested.

Squash Bug.—The squash bug is often a serious problem in the growing of squash and pumpkins. This insect is a grayish black "stink bug" about three-fourths of an inch long when mature and is grayish or greenish gray when young. The eggs are bronze in color and are usually found on the upper sides of the leaves. Both the adults and young feed by sucking the sap from the leaves and stems and may interfere with normal sap flow. Small plants are quickly killed, while the leaves and vines of older plants wilt and often die.

Control is difficult as nicotine sprays have no effect on the adults and but little on the nymphs. Practices, such as destruction of crop remnants in the fall and hand picking of adults and eggs, will aid in reducing damage from these pests.

Squash Vine Borer.—Much of the loss on squash and pumpkins attributed to squash bugs and disease is caused by a white, grub-like borer found working at the base of plants. This borer is the larval stage of a clear-winged moth. Eggs are deposited on the stems of the plant and shortly after hatching, the small caterpillars bore into the stems. Their feeding cuts off the water and food supply, causing the leaves to wilt as if attacked by the wilt disease. Often two to 20 borers are found feeding in the base of one plant.

Control.—Since these insects feed inside the the stems, except for the first day or so after hatching, poisons are of little value against them after they burrow into the shoots. However, a 4-4-50 Bordeaux spray, with 1½ pounds of arsenate of lead added, applied at five- or six-day intervals, starting shortly after the plants come up and continuing for two or three weeks, will give effective control. Destruction of the vines immediately after the gathering of fruit will kill many borers. Cultivation of the ground in the fall where squash have grown will bring up and expose many of the cocoons. In the home garden the borers can be dug out of the stem with a sharp knife. Moist soil should be placed over the base of the plant after destroying the borers, to give them a chance to form new roots.

INSECT PESTS OF MINT

The insect enemies of the mint crop are discussed in some detail in Purdue Circular No. 211. Of the many pests attacking peppermint and spearmint, the mint flea beetle is the only major pest, while occasionally millipeds, cutworms and white grubs cause some damage.

Mint Flea Beetle.—The mint flea beetle is a new pest in Indiana but has now become established in all mint-growing areas. In the adult stage the small light brown beetles feed on the terminal foliage, while the small white worm-like grubs feed on the roots of the plant. It is essential for every grower to watch for indications of this pest in order that he may understand the relation between life history and control measures. This pest passes ten or eleven months of each year in the soil and so cultural practices and insecticide applications must be carefully timed.

The adult beetles start emerging from the soil early in July, with a peak of emergence usually around the middle of the month. They feed for ten days or two weeks before mating and egg deposition. The eggs, which are laid in the soil near the roots, remain here until the following spring when the small, white larvae hatch and commence feeding on the small rootlets. The larval stage lasts until the middle of June when they undergo a pupal or resting stage before emerging from the soil as adult beetles in July.

Injury to the roots is often hard to recognize by examining the foliage of the plants. With only a moderate amount of feeding on the roots, the foliage becomes reddish in color similar to frost injury. In cases of severe injury the foliage changes to a brownish color and often dies. The larvae when small feed on the smaller roots but later often girdle and tunnel into the large roots. Such feeding, of course, prevents the natural spread of the roots. The beetles feed upon the foliage, especially the terminal growth. Feeding occurs during the cooler portions of the day, the beetles remaining on the lower leaves, the stems or ground under the plant when the sun is bright. The beetles eat small, round holes in the leaves which will often cause them to drop when feeding is excessive.

Control.—Insecticide applications must be timed so that the poison is on the foliage when the majority of the beetles have emerged from the soil and *before* the females start to lay eggs. This period in normal seasons is between July 20 and August 5 for most Indiana mint sections or approximately 15 days after the first beetles appear. On growing mint the best material to use is calcium arsenate, which is applied undiluted, or with 5 to 10 per cent bentonite, at the rate of 15 to 20 pounds per acre. After the mint is harvested, a Paris green-flour mixture at a 1 to 9 dilution is safe to use, and gives a better kill, but it cannot be used on growing mint. Either mixture should be applied early in the morning when the air is calm and the plants moist with dew.

When the standing mint is dusted with calcium arsenate, it should not be used as hay for animals after the oil is distilled from it. In those seasons when insecticide applications will interfere with the normal harvesting of the crop, it is advisable to cut the mint a week or so early. Then the Paris green mixture can be applied to the mint stubble at the proper time to obtain the most efficient results. Special care should be taken to prevent infestation of first-year mint. When ready to cut a field of meadow mint adjoining row mint, a 20-foot border strip should be thoroughly poisoned and left uncut to kill the beetles as they migrate from the stubble.

Infestations in new fields are often started by carrying some stage of the insect on the roots used in setting out the new area. In that portion of the farm where plants for transplanting are to be obtained, special care should be taken to kill all beetles. At least three applications should be made to such areas. In digging the plants for transplanting, as much soil as possible should be shaken from the roots.

INSECT PESTS OF POTATOES

Potato Leafhopper.—The most destructive pest of potatoes on muck soils is the potato leafhopper. This small insect has sucking mouthparts and through its feeding causes a pathological condition, a dying of the plant cells,

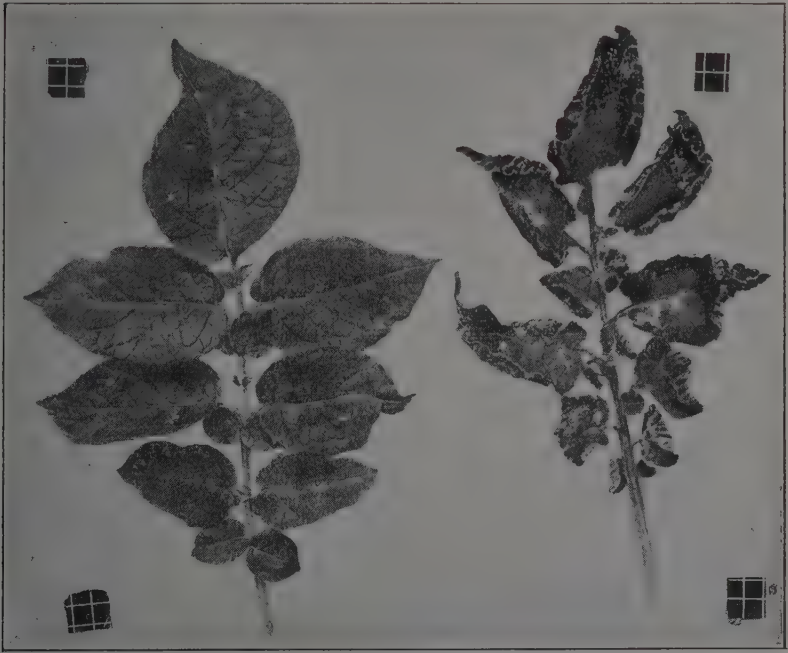

Fig. 10. The feeding of leafhoppers on potato foliage is toxic to the plant cells, causing curling and browning of leaves as shown at right. (After Parrott.)

known as hopperburn. Although more damage is caused to potatoes than any other crop, this insect also feeds on beans, apples and a number of cultivated and wild plants. Hopperburn first appears on the edges of the leaves as a browning dying area followed by curling and eventual death of the entire and eventual death of the leaf. (Fig. 10.) This condition is not caused by a disease organism and does not spread from leaf to leaf through the sap, but appears only after the feeding of the leafhoppers. In case of severe infestations the entire plant is affected and often dies two to four weeks prematurely.

These leafhoppers are small, greenish-white insects, very active and capable of jumping or flying when disturbed. The young resemble the adults except that they lack wings and cannot fly. Both stages are found on the under surface of the leaves. There is some question as to where these insects hibernate during the winter, but in the spring they suddenly appear in large numbers on weeds. After a generation here, there is a definite migration to apples and during late June still another migration to potatoes and beans. Eggs are laid in the stems or veins of the host leaves. As a rule leafhoppers cause little damage to the early potato crop as they do not migrate to them until shortly before the normal death of the plants. On late potatoes in Northern Indiana there are usually two generations a year, and damage is often severe.

Control.—Both the leafhopper and hopperburn are usually controlled through the use of Bordeaux spray or copper-lime dust. In a series of tests conducted over a period of five years on late potatoes at Goshen, the 4-6-50 Bordeaux spray applied five times at 10- to 14-day intervals gave increases in yield sufficient to show a very good profit over and above the additional cost involved in the treatment. A 20-80 copper-lime dust, while not so good as the spray, also gave yields that showed a net profit.

The Bordeaux spray should be freshly prepared before each application and is made as follows: dissolve 4 pounds of copper sulphate in a portion of the water and pour into the spray tank. Mix 4 to 6 pounds of chemical hydrated lime in sufficient water to make a thin paste and add to solution in tank while the agitation is running. Then add the remainder of the 50 gallons of water. Copper sulphate can now be purchased in a powdered form which dissolves readily in water and does not necessitate the over-night soaking of the lump form. Bordeaux spray should be applied at a rate of 100-125 gallons per acre with at least 200 pounds of pressure. The sprayer should have three nozzles per row, one for the top and one on each side.

A 20-80 copper-lime dust can be purchased ready-mixed or can be mixed at home. In mixing, 20 pounds of *fresh monohydrated* copper sulphate and 80 pounds of fresh hydrated lime are thoroughly combined. All materials should be kept tightly sealed until ready for use and should be purchased fresh each season. This dust must be applied early in the morning when the air is calm and the plants are wet with dew. The first application should be made when the plants are four to six inches high and at a rate of 20 pounds per acre. As the plants increase in size, the amount should be increased to about 35 pounds per acre.

A regular dust or spray schedule should be carried out every year on late potatoes, regardless of the presence or absence of leafhoppers. Although yields on the early crop seldom are increased sufficiently to pay for the extra cost involved, treatment of the late crop has always resulted in increased yields. Copper applied to the leaves in same way acts upon the plant and stimulates them to produce additional foliage. In New York State it has been found that the copper content should be high on the first application and reduced later. No treatments should be made after September first, in order to allow for maturity of the tubers.

Colorado Potato Beetle.—The globular yellow and black striped adults and brick-red grubs of the Colorado potato beetle (Fig. 11) are well known to most potato growers. As a rule, the damage from this pest is more serious on early potatoes.

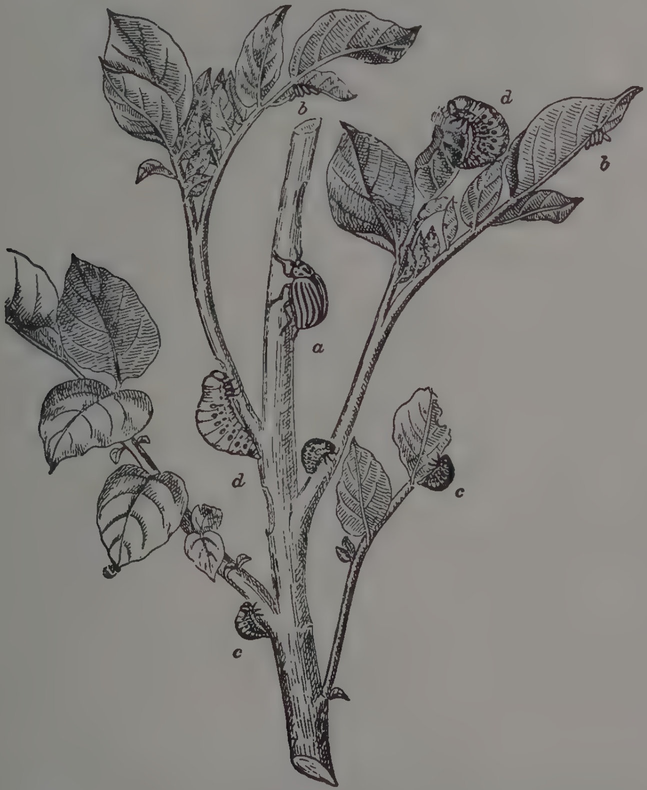

Fig. 11. The common yellow and black striped Colorado potato beetle attacks the foliage of potatoes in the larva and adult stages. (After Chittenden, U. S. D. A.)

Control is rather simple as the beetles and grubs are slow-moving and feed readily on poisoned foliage. For spraying arsenate of lead can be used alone in water or in Bordeaux at a rate of 1½ pounds to 50 gallons. For dusting calcium arsenate is used with lime in a 1 to 5 dilution or in a copper-lime dust formula of 20-20-60, where the first figure indicates the poison.

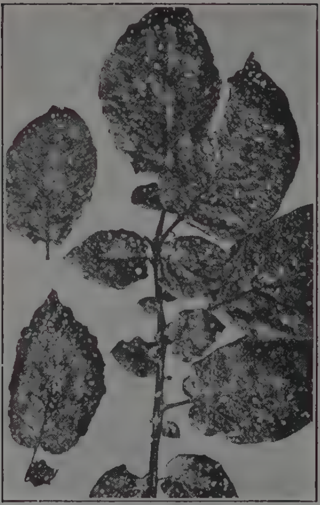

Fig. 12. Flea beetles eat small holes in the foliage.

Potato Flea Beetle.—These small, black, jumping beetles are occasionally injurious to muck potatoes. They injure the potato foliage by eating small circular holes (Fig. 12), while their small, white larvae tunnel on the surface of the tubers.

Control.—The beetles are controlled by the use of the poisoned copper-lime-dust or Bordeaux spray, prepared as indicated under the Colorado potato beetle.

Blister Beetles.—Blister beetles of several varieties may migrate into a portion of the field and rapidly strip the potato plants of foliage. The common, long black and yellow striped beetle is known as the old-fashioned potato beetle, while gray and black varieties also feed on potatoes.

Control.—These insects are repelled by the presence of arsenicals and lime on the foliage. Barium fluosilicate diluted with equal parts of dusting clay or flour will give excellent control, but should not be applied to plants coated with other insecticides or when the plants are wet.

White Grubs.—White grubs are frequently serious pests of corn, potatoes, and many vegetable crops on land which has been in sod within two years. These insects, which in the adult stage are common June beetles, have a three-year cycle, most of which is spent in the soil. The beetles feed on many kinds of trees and lay eggs in nearby sod or grassland. The grubs prefer the roots of grasses and corn but do feed upon a number of other plants. (Fig. 13). The first two seasons following the plowing of sod land may see considerable damage to susceptible crops.

Control.—Since these pests spend most of their life in the soil, control is difficult. Rotation of crops is important and susceptible crops such as corn, strawberries, potatoes and root crops should not be planted in sod land for at least two seasons after plowing. Certain legume crops and some vegetables suffer but little damage from the grubs. Early fall plow-

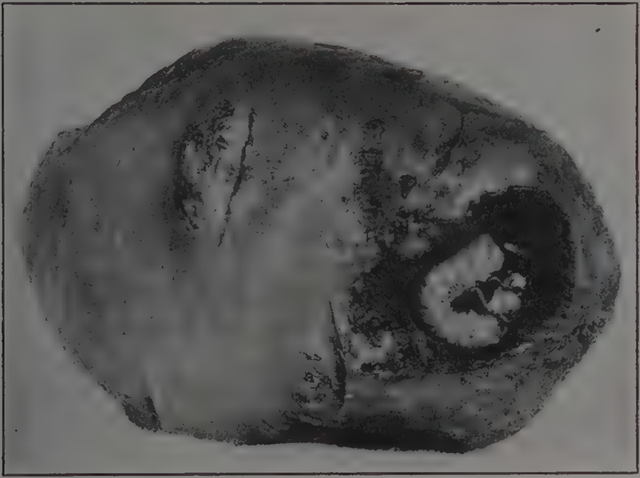

Fig. 13. The common white grub cuts off the roots of most muck crops and eats into the tubers of potatoes. (After Davis, U. S. D. A.)

ing before the grubs go down for the winter will expose them to birds and other predators.

Wireworms.—Wireworms of several different varieties are frequently common in muck soils. In some respects they resemble the white grub in habits as they have a long life cycle (two to five years) and all but a month or so of this time is spent in the soil. Wireworms are hard, brownish, wiry worms about an inch long, while the adult is the common click or "snapping" beetle. The larval stage prefers to feed on the roots of grass crops and will burrow into potato tubers. The injury on potatoes consists of holes usually less than ¼ inch in diameter eaten into the tubers, while injury by white grubs is larger but shallower.

Control.—Control of wireworms is difficult and depends largely upon cultural practices. Rotation, using a legume if possible, and early fall plowing are of some value. As a rule, wireworms are associated with poor drainage and the correction of this trouble will often eliminate damage. The adult female lays her eggs during May and June in the soil of grassy or weedy land. If the soil is bare of all vegetation during this egg-laying period, the females will avoid this land. Crops should be thoroughly cultivated to eliminate grass. Bait crops, in which rows of wheat, corn or cull onions are planted in severely infested fields, are of some value. A week after placing the baits the wireworms in the nearby soil will have collected about them and can be dug up and destroyed or may be killed by drilling calcium cyanide along side the bait crop.

Millipeds.—Millipeds (Fig. 14) are not insects, but belong in a closely related group of animals, characterized by having two pair of legs on each body segment. They are usually dark brown in color, round in cross section, and have a length of one to two inches. When disturbed they quickly curl up in a tight roll. These pests prefer soils with a high organic content and

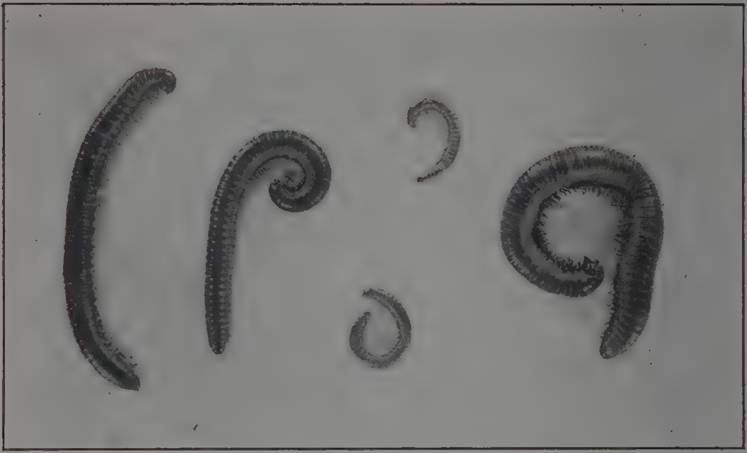

Fig. 14. Millipeds are common in many muck soils and are especially injurious to potato tubers.

especially those where crop remnants have been plowed under or soil conditions are moist. Their food consists of various organic substances in the soil and in some instances roots of plants are attacked. Damage to potatoes on some Indiana muck farms has ran as high as 50 to 60 per cent of the tubers.

Control.—Millipeds live in the soil year after year and are exceedingly difficult to eradicate. Thorough summer fallowing of heavily-infested muck land is advisable. Green crops, manure, and plant debris should not be plowed under, if at all possible to avoid. Highly acid soils are avoided by millipeds. Soils with a pH reaction of around 5 have little trouble from these pests, but with a pH 5.5 and above, millipeds will multiply rapidly if they ever become established. Sulphur has been used a great deal in the past few years to acidify the soil, but should be used only after careful tests of the soil. Acid forming fertilizers are also of value on soils with a reaction of not over pH 6.0.

INSECT PESTS OF ONIONS

A number of insects attack the onion crop and two, the onion thrips and the onion maggot, cause losses almost every year. Chemical control measures, however, are not entirely effective and supplementary measures must be relied on to keep insect population at a minimum.

Onion Maggot.—Onion maggots occasionally cause severe damage to the onion crop, especially in damp seasons. This insect in its adult stage is a small, dull-gray fly, somewhat smaller than a house fly, and as a larvae is a small, white, legless maggot. The winter is passed in a brown puparium in the soil in old onions or in the onion screening pile. In late April and May the flies emerge and lay their eggs in the soil near the small seedling onions. On hatching the small maggots eat into the small onions near the base. Frequently the maggots will leave the first onion and bore into a second and sometimes a third onion. These small onions may be killed outright by the feeding of the larvae, or rot organisms may enter through the injuries made by the maggot. Injury is much more severe on the pickling onions or onions grown for sets as in these cases the seed is planted thick and one insect can work into a number of closely crowded plants. Damage is always more severe during May as the plants are then small and that brood of maggots is usually the largest. The second and third generations are rarely of importance.

Control.—Control of the onion maggot with a Bordeaux-oil emulsion spray is successful if applied at the proper time. However, this insect does not appear in destructive abundance every season and the spray causes some burning on the small onion seedlings. No method has been devised whereby maggot abundance can be predicted in advance, so cultural practices must be relied upon to hold this pest in check. Cull onions should be removed from the fields as soon after harvest as possible, and should never be spread back on the land for fertilizer. The piles of culls and of onion screenings should be drenched with used crank-case oil and burned by March 1.

Onion Thrips.—Damage by onion thrips occurs annually in some portions of the Northern Indiana muck section. Usually losses are greater on the so-called "higher mucks" in the northeastern part of the state. However, growers in this section claim that the thrips cause them no loss but actually aid in "maturing" their onions at the proper time. Onions injured by thrips are characterized by a silvery appearance of the plants. A hot, dry season is favorable for a rapid increase of these small pests and the first evidence of injury begins to show in early June. From then on, the insect and the injury increase rapidly until late July or early August when the plants are killed. Onion yields are often reduced as much as 50 per cent.

Thrips overwinter on a wide variety of wild and cultivated plants growing in and about the onion fields. In the spring the adults migrate to green plants and feed and reproduce these. As the onions come up, thrips start feeding on these plants and rapidly produce several generations. In their development the young feed for several days and then undergo a resting stage, either in the soil or between the leaf sheaths. During the early part of the day few insects are to be seen but in late afternoons most of them come out to feed. There are at least six generations of this insect a year.

Control through the use of insecticides has never proved to be entirely successful. Thrips have a rasping type of mouthpart which is intermediate between chewing and sucking. Contact sprays, such as nicotine, have been widely recommended and used, but because of the habit of the insects of living between the tightly fitting leaves, these materials have given only a moderate degree of success. Experiments are being continued using various contact materials as well as some of the repellent dusts and sprays.

Perhaps the best hope for a solution to the thrips problem is the development of resistant or tolerant varieties of onions. At present one commercial variety, the Sweet Spanish onion, has proved to be decidedly tolerant to thrips attack. This onion has both a vigorous root system and large sturdy neck and tops, and can withstand the feeding of thrips that would kill other types of onions in a short time. While the Sweet Spanish type may never replace common Southport varieties because of poor keeping qualities, growers are planting an increased acreage of them each year. Further studies on the factors of resistance and tolerance in onions are being continued in many parts of the country.

Cultural practices play an important part in the elimination of thrips. Set onions with their early start in the spring are the first hosts of the strips and from here they migrate to the later seed onions. It is important, therefore, to plant the seed onions as far from the set onions as possible. Clean cultivation of the field is important as these pests feed on many weeds. Weeds and plant debris along the fence rows and ditch banks should be destroyed in the fall as they afford thrips ideal hibernating quarters.

TWENTY-SECOND ANNUAL REPORT OF THE CREAMERY LICENSE DIVISION

T. H. BINNEY

Indiana Dairy Statistics

At the time of applying for the renewal of creamery licenses, all creameries, milk plants, cheese factories, condenseries, etc., report the amount of butter, milk, cheese, or other dairy products made or sold during the year. With this information, together with figures supplied through a co-operative agreement with the United States Department of Agriculture, Bureau of Agricultural Economics, it is possible to compile reliable statistics concerning the total production of licensed dairy manufacturing plants.

The following table is a summary of the reports received from licensed plants for the years indicated:

Output of Licensed Plants in Indiana for 1914, 1924, 1934 and 1935.

	1914	1924	1934	1935
Pounds of Butter	26,636,520	53,462,104	77,061,858	73,934,938
Pounds of Milk	51,067,066	257,417,090	486,921,912	473,718,006
Pounds of Cream	5,421,838	25,219,252	27,640,066	22,184,720
Gallons of Ice Cream	2,035,874	4,865,465	3,346,232	3,810,368
Pounds of Cheese	211,922	574,686	23,362,975	22,225,598
Pounds of Sweetened Condensed Milk	1,019,400	8,735,498	2,733,998	1,536,790
Pounds of Evaporated Milk	10,106,800	23,912,054	41,175,957	38,688,310
Pounds of Unsweetened Condensed Milk	2,450,988	19,065,245	22,095,158	29,784,737

By comparing the figures for 1934 with those of 1935 in the above table, it will be noted that with the exception of unsweetened condensed milk and ice cream all products show a decrease. The decrease in the amount of butter made is 3,126,920 pounds, or 4.0 per cent. A total of 473,718,006 pounds of milk and 22,184,720 pounds of sweet cream were sold in licensed plants during the past year. This represents a decrease of 2.7 per cent of milk and 19.7 per cent of cream in 1935 as compared with 1934. The amount of ice cream manufactured during the past year shows an increase of 464,136 gallons, or 13.8 per cent. Cheese production decreased 1,137,377 pounds, or 4.0 per cent. Sweetened condensed milk decreased 1,197,208 pounds, or 43.7 per cent; evaporated milk (case goods) decreased 2,487,647 pounds, or 6.0 per cent, and unsweetened condensed milk increased 7,689,579 pounds, or 34.8 per cent.

In addition to the above products, dairy plants of the state manufactured 17,012,050 pounds of sweetened condensed skim milk; 1,563,255 pounds of unsweetened condensed skim milk; 745,317 pounds of concentrated skim milk (for animal feed); 9, 707,806 pounds of condensed or evaporated buttermilk; 3,584,857 pounds of dried or powdered skim milk, and 1,320,263 pounds of dried or powdered buttermilk.

The following table gives the amount of milk which goes into the various dairy products handled in licensed plants:

DISTRIBUTION OF MILK IN LICENSED PLANTS

Creamery Butter Used	1,552,633,693 pounds or	59.5%
Cheese Used	222,255,980 pounds or	8.5%
Ice Cream Used	52,392,560 pounds or	2.0%
Condensed and Evaporated Used	175,024,592 pounds or	6.7%
Cream Used	135,272,609 pounds or	5.2%
Milk Used	473,718,006 pounds or	18.1%
Total	2,611,297,445 pounds or	100.0%

CREAMERY LICENSES

Every creamery, shipping station, milk factory, cheese factory, or person, agent, firm, company, association or corporation, receiving, buying and paying, for milk or cream on the basis of the amount of butterfat contained therein, shall be required to hold a creamery license. (Section 6, Chapter 340, Acts of 1913, Indiana). The license is issued by the Purdue University Agricultural Experiment Station upon complying with the provisions of the Indiana Creamery and Testers' License Law. Such license is valid for a term of one year unless revoked by the Purdue University Agricultural Experiment Station.

During the past year 1,722 creamery licenses were issued. This is a decrease of 67 from the previous year's total of 1,789. Plant licenses show a gain of 13 in number, while the number of station licenses show a decrease of 80.

The following table is a summary of the kind of plants issued creamery licenses during the year ending March 31, 1936, and for previous years, as indicated.

CREAMERY LICENSES ISSUED FROM 1930-1935 INCLUSIVE

Plants and Stations	Number and Year					
	1930	1931	1932	1933	1934	1935
Butter	56	58	57	56	56	60
Milk	162	147	162	175	172	186
Ice Cream	18	16	12	14	14	13
Cheese	18	19	18	22	26	31
Condensed Milk	8	10	10	11	13	12
Butter and Milk	36	46	54	51	61	51
Butter and Ice Cream	10	13	9	11	5	7
Butter and Cheese	1	2	3	2	5	4
Butter, Milk, and Ice Cream	20	17	23	26	25	25
Butter, Milk, and Condensed Milk	7	6	2	4	2	1
Butter, Milk, Cheese	0	0	0	0	2	3
Butter, Milk, Ice Cream, Condensed Milk, and Cheese	0	0	0	0	1	2
Butter, Milk, Ice Cream and Condensed Milk	6	6	7	5	5	5
Butter, Ice Cream, Cheese	0	1	1	1	3	4
Butter, Milk, Cheese and Condensed Milk	0	0	1	1	1	1
Milk and Ice Cream	19	26	25	19	26	25
Milk and Condensed Milk	4	5	4	3	1	1
Total number of Plants	369	372	389	401	418	431
Stations	1,524	1,457	1,363	1,355	1,371	1,291
Total Licenses Issued	1,893	1,829	1,752	1,756	1,789	1,722

The following table shows the number of plants which reported each of the five major products handled in licensed plants for the years indicated.

Product	Number of Plants Reporting					
	1930	1931	1932	1933	1934	1935
Butter	136	149	158	157	166	163
Milk	257	254	279	284	296	305
Ice Cream	76	79	77	76	79	81
Cheese	20	22	22	26	38	45
Condensed Milk	28	31	25	24	23	22

TESTERS' LICENSES AND EXAMINATIONS

To insure accurate tests to the producer and manufacturer, licensed testers are employed by all plants and stations where milk and cream are bought on a butterfat basis.

Before securing a license an operator must pass an examination which consists of both laboratory and written work. The laboratory work consists of testing samples of milk and cream in duplicate; the written work consists of answering twenty questions which pertain to the testing of milk and cream.

Five hundred and eighteen candidates appeared for the testers' examination during the past year. This is an increase of ninety-six candidates over the previous year. Out of this number fifty-five failed to receive a passing grade; thirty-four of the failures were due to unsatisfactory written work, nine were due to laboratory work and twelve were due to both written and laboratory work.

Twenty hundred and twenty-five testers' licenses were issued during the past year, a decrease of fifty from the previous year's total of twenty hundred and forty.

The following table shows the number of candidates examined and testers' licenses issued for the years indicated:

NUMBER OF CANDIDATES EXAMINED AND TESTERS' LICENSES ISSUED FOR THE YEARS ENDING MARCH 31, 1920, 1925, 1930, 1935, AND 1936

	1920	1925	1930	1935	1936
Number of Individual Examinations	1,339	830	691	512	518
Number of Failures	226	166	144	53	55
Number of Persons Passing Examinations	1,113	664	547	459	463
Number of Testers' Licenses Issued	2,371	2,523	2,562	2,075	2,025

The results of the forty-four examinations which were held at the seven examination points in the state are given in the following table:

RESULTS OF TESTERS' EXAMINATIONS 1935-1936

PLACE OF EXAMINATION	Number of Examinations	Number of Candidates	AVERAGE GRADES (PER CENT) All Candidates	Candidates Passed	Candidate Failed
Lafayette	8	165	82.6	85.1	51.5
Muncie	6	56	80.5	83.8	46.3
Fort Wayne	6	58	84.0	85.4	42.0
Evansville	6	65	78.3	80.9	66.3
Terre Haute	6	41	81.6	83.4	57.2
Indianapolis	6	50	82.2	84.0	65.1
Seymour	6	83	79.1	83.3	63.8
Totals	44	518	81.2	83.7	56.7

GLASSWARE INSPECTION

The Indiana Creamery and Testers' License Law requires that all milk and cream test bottles, milk pipettes, and nine-gram weights be examined for accuracy by the Purdue University Agricultural Experiment Station before being used in Indiana cream stations and dairy plants. All glassware conforming to the specifications given in Section 13 of the Law (Acts of 1913, Chapter 340) and found to be within the allowable tolerance are stamped with the letters "S.G.P." meaning "Standard Glassware, Purdue". The use of standard inspected glassware eliminates the possibility of incorrect tests from this source.

During the past fiscal year 39,280 pieces of Babcock testing glassware were examined by the Glassware Inspector of the Agricultural Experiment Station. In addition, 314 nine-gram weights were inspected and found to be correct. This is 6,100 less pieces of glassware and 139 more nine-gram weights than were inspected last year.

The following table gives the amount of each kind of glassware inspected, and the number of pieces found to be incorrect:

KINDS OF GLASSWARE	Total Number of Pieces	Number Incorrect	Per Cent Incorrect
Cream Test Bottles	27,132	22	.081
Milk Test Bottles	8,531	0	.000
Milk Pipettes	3,617	0	.000
Summary	39,280	22	.056

LICENSES REVOKED

Inspectors of the Creamery License Division check the weights and tests made by operators of the Babcock test to determine their accuracy. If an operator is found to be testing incorrectly the inspector cautions him to be more careful in the sampling, weighing, and testing of milk and cream. Should later inspections show that incorrect testing is being done, whether intentionally or unintentionally, evidence is secured and presented to the State Creamery Examining Board at one of their regular meetings. At this meeting the operator is given an opportunity to explain the cause for differences between his tests and the tests made by the inspector. After careful consideration of the facts presented, the Board recommends to the Purdue University Agricultural Experiment Station the action to be taken.

During the past year the following testers were requested to appear before the Examining Board and, after considering the evidence, the Board recommended that their testers' licenses be revoked:

Mrs. Waty Herron, Cory, Clay County, Indiana, tester for Highland Creamery Company, Terre Haute, Indiana.

Mr. Howard Hockett, Lynn, Randolph County, Indiana, tester for Sherman White and Company, Fort Wayne, Indiana.

Miss Cora Hubbell, Coal City, Owen County, Indiana, tester for Johnson Creamery Company, Bloomington, Indiana.

Mr. Harold Rickert, Saratoga, Randolph County, Indiana, tester for Farm Bureau Creamery, Portland, Indiana.

Mr. Henry Welkie, Wanatah, LaPorte County, Indiana, tester for Kosanke Brothers, Argos, Indiana.

Mrs. Grace Hayward, Liberty, Union County, Indiana, tester for Sherman White and Company, Fort Wayne, Indiana.

Mrs. Hurma Parker, Farmland, Randolph County, Indiana, an independent buyer.

Mrs. Pearl Worster, Warren, Huntington County, Indiana, tester for Schlosser Brothers, Frankfort, Indiana.

Mr. Raymond Ahles, Evansville, Vanderburg County, Indiana, tester for Edgewood Dairy, Evansville, Indiana.

Mr. Marion Abell, Madison, Jefferson County, Indiana, tester for Ewing-Von Allmen Dairy Company, Louisville, Kentucky.

Miss Roberta Rasure, Evansville, Vanderburg County, Indiana, tester for Sugar Creek Creamery Company, Evansville, Indiana.

Mr. C. W. Leslie, Evansville, Vanderburg County, Indiana, tester for Sugar Creek Creamery Company, Evansville, Indiana.

Miss Genevieve Snyder, Zanesville, Wells County, Indiana, tester for Zanesville Creamery, Zanesville, Indiana.

Mr. E. L. Bishop, Connersville, Fayette County, Indiana, tester for City Dairy, Connersville, Indiana.

Mr. F. H. Carpenter, Dale, Spencer County, Indiana, tester for Kraft-Phenix Cheese Company, Dale, Indiana.

Circular No. 225 November, 1936

INSPECTION OF AGRICULTURAL SEEDS

A Section of the Indiana Seed Laboratory where Purity Tests of Seeds are made by Trained Analysts.

AGRICULTURAL EXPERIMENT STATION
PURDUE UNIVERSITY
LAFAYETTE, INDIANA

4

Otis Sidney Roberts, Inspector in the Department of the State Chemist and State Seed Commissioner for more than twenty-eight years including twenty-five years as Chief Inspector and one year as Acting State Chemist and State Seed Commissioner, died December 19, 1935. In the passing of Mr. Roberts, the seed, feed and fertilizer industries, as well as the agricultural interests of Indiana, have suffered a distinct loss of a loyal friend and an able worker.

Herein is presented a report of the Agricultural Seed Inspection for the year from July 1, 1935, to June 30, 1936. The complete analyses of 1,362 official seed samples are given in detail. In addition 318 official samples drawn for test and 3,069 free test samples of seed were tested during the year.

Violations of the Indiana Seed Law and of the Federal Seed Act are discussed together with helpful suggestions to seed dealers and seed purchasers.

This Circular also contains the Rulings of the State Seed Commissioner, discussions on free testing of seeds, directions for taking samples and directions for making germination tests at home.

Statements concerning Stained, Certified, Verified-Origin and Affidavit seed are given.

Tables 1 to 7 show in a general way the quality of the seed represented by the official samples while Table 8 gives in detail the analyses of the 1,362 official samples.

INSPECTION OF AGRICULTURAL SEEDS

H. R. KRAYBILL, State Seed Commissioner
P. B. CURTIS, Associate Chemist
A. S. Carter,* Chief Inspector. Regina B. Schulte,† Seed Analyst
Assistant Seed Analysts: Pauline Balbach, Mary E. Grey
Assistant Inspectors: C. M. Cohee, J. W. Jackman

The Indiana Seed Law enacted in 1921 is an Act to regulate the sale of and commerce in agricultural seeds. The purpose of this law is to give the purchaser of seeds sufficient information to enable him to buy good seed and also to protect the honest seed dealer and the farmer against the practices of dishonest, careless and irresponsible seedsmen. This is accomplished by requiring the seed that is sold or offered for sale within the state for seeding purposes to be labeled with Official Indiana State Seed Tags showing minimum percentages of purity and germination and the maximum number per pound of each of the noxious weed seeds. Table 5 on page 12 lists the weed seeds that are considered noxious under the Indiana Seed Law. The date of the germination test and state or foreign country in which the seed was grown must also be designated on the tag.

In addition to the tagging requirement the Indiana Seed Law provides for inspection and testing of samples of seed to determine whether or not the statements of the seedsmen on the tags are correct. Inspectors secure representative samples from shipments or lots of seed offered for sale in all sections of the state. These samples are then forwarded to the seed laboratory where they are tested.

RESULTS OF INSPECTION

During the year from July 1, 1935, to June 30, 1936, 1,680 official seed samples were collected and tested. Reports of these tests were sent to the distributors, dealers, and consumers from whom the samples were secured. In addition 3,069 free test samples and 71 Custom House samples were analyzed. The testing of all of these samples entailed the making of 3,376 purity tests, 20,648 individual germination tests, 30 examinations and 156 identifications. Of the 1,680 official samples, 318 of them were drawn and tested upon request of seedsmen in order that they might know the percentages of purity and germination and the number per pound of each of the noxious weed seeds to list on their tags. Of the remaining 1,362 samples, 234 of them were found to be seriously misbranded. This represents 17.2 per cent of the samples as compared to 18.1 per cent in the preceding year. This is a good record considering the fact that 65 of the 234 samples were samples of corn seriously misbranded as to germination. Due to the wet weather in the fall of 1935 and severe early freezes in the winter a large portion of the seed corn in the spring was so seriously damaged that it was difficult for the seedsmen to make accurate statements of germination unless special care was taken to conduct individual ear tests. This unusual circumstance necessitated the testing for germination of the greatest number of official samples of corn ever tested in a single year in the history of the Indiana Seed Law. Due to the inferior condition of the seed corn the department was called upon to investigate many cases where poor results were obtained and was instrumental in securing adjustments.

---

* Appointed Chief Inspector, effective February 1, 1936.

† Assistant Botanist, in coöperation with the Division of Seed Investigations, Bureau of Plant Industry, U. S. D. A.

In addition to testing seeds the seed laboratory in coöperation with the Agronomy Department conducted a three weeks' intensive course in official methods of seed testing from June 29 to July 18, 1936. Twelve persons were enrolled in this course.

VIOLATIONS OF THE INDIANA SEED LAW

Violations of the Indiana Seed Law may be divided into two classes: first where the seed is sold or offered for sale without Official Indiana State Seed Tags, and second where the seed is tagged but fails to meet the seedsman's claim stated on the tags. In both of these cases shipments or lots of seed were removed from sale until proper tags had been attached to cover the particular seed in question. During the past year six cases of non-tagging and one case of misbranding were called to the attention of the prosecuting attorneys. Five of these cases resulted in convictions and payment of fines while two cases have not been reported upon by the prosecuting attorneys.

VIOLATIONS OF THE FEDERAL SEED ACT

Under the Interstate Clause (Sec. 6) of the Federal Seed Act seven cases were reported to the Division of Seed Investigations of the Bureau of Plant Industry of the United States Department of Agriculture.

The following excerpt concerns the disposition of a previous seed case submitted:

Prosecutions and Seizures Under the Interstate Clause (Sec. 6) of the Federal Seed Act Jan. 1, 1935, to June 30, 1935.

73. Misbranding of sweet clover seed. U. S. v. American Field Seed Co Plea of guilty. Fine, $200. (F. S. 120).

American Field Seed Co., Chicago, Ill., shipped on March 27, 1934, from Chicago, Ill., to Remington, Ind., 2 bags (300 pounds) of sweet clover seed

Information was filed in the United States District Court for the Northern District of Illinois alleging that the American Field Seed Co., a corporation unlawfully delivered for transportation in interstate commerce the above mentioned shipment misbranded in violation of the Federal Seed Act.

NATURE OF MISBRANDING

Item	Claimed Per Cent	Found Per Cent	Item	Claimed Per Cent	Found Per Cent
Purity	99.50	94.32	Weed Seeds	0 10	1.26
Inert Matter	0.30	4.29	Germination	92 00	64.00

On December 6, 1934, the case was terminated upon a plea of guilty and the assessment of a fine of $200.

TOLERANCES

Under the most perfect and approved conditions of testing seeds, variations will occur in purity and germination tests. For this reason the Association of Official Seed Analysts, whose methods of testing are followed in this seed laboratory, has adopted tolerances or allowances for purity and germination tests. Samples of seed with a claim within the tolerances are not considered to be misbranded under the provisions of the Indiana Seed Law, but seed dealers are expected to change the claim on the tags of the unsold portion to correspond to the analysis found by the Seed Commissioner.

(a) Purity Tolerance.—In determining the tolerance for purity the sample shall be considered as being composed of two parts: (1) pure seed of the kind certified and (2) everything not pure seed. The tolerance permitted shall be two-tenths of 1 per cent (0.2%) plus 20 per cent of the lesser part. Example: Seed marked 98 per cent pure, the lesser part is 100 minus 98 or 2. Twenty per cent of 2 equals 0.4. Therefore, the tolerance allowed would be 0.2 plus 0.4, or 0.6%.

(b) Germination Tolerance.—A larger tolerance is applied between a given germination and the result of the germination test as follows:

Given Germination (Per Cent)	Allowable Variation (Per Cent)
90 or over	6
80 or over but less than 90	7
70 or over but less than 80	8
60 or over but less than 70	9
Less than 60	10

RULINGS OF THE STATE SEED COMMISSIONER

In accordance with the provisions of the Indiana Seed Law empowering the Seed Commissioner to prescribe and enforce such rules and regulations as he may deem necessary to carry into effect the full intent and meaning of the Act the following rulings have been made:

Ruling No. 1. Hard Seeds. The phrase "minimum percentage of germination," as contained in the Indiana Seed Law, is interpreted to mean the actual percentage of the seeds that sprout or germinate at the end of the time usually allowed for germination test. In the case of leguminous seeds containing "hard seeds," the actual percentage of germination should be given on the official label and this germination percentage may be followed by the percentage of hard seeds. For example, the seed showed 85 per cent actual germination and in addition contained 10 per cent hard seeds. This may be stated on the label as 85 per cent germination and 10 per cent hard seeds. This cannot be stated as 95 per cent germination and 10 per cent hard seeds.

Ruling No. 2. Tagging. All agricultural seed in condition for seeding purposes shipped or delivered in the State of Indiana must have attached to each bag or package of one pound or more an Indiana State Label properly filled out.

The wholesale seedsman is required to attach at least one Indiana State Tag properly filled out to each package of one pound or more of seed shipped to the retail seedsman. The retail seedsman is then required to attach sufficient tags to the seed to cover its net weight before offering or exposing the seed for sale. If the seed is shipped directly to the consumer, sufficient Indiana State Tags must be attached to cover the net weight of the seed.

Ruling No. 3. Hybrid Corn. Field corn, sweet corn or popcorn offered or exposed for sale for seeding purposes in the State of Indiana may be labeled or represented to be *hybrid corn* only when such seed represents the first generation of a cross between strains of different parentage and involving inbred lines of corn and/or their combinations.

FARMERS' EXEMPTION

A farmer is exempt from the provisions of the seed law when the seed is grown, sold and delivered by that farmer on his own premises to the purchaser himself. If, however, the seed is advertised for sale by the public press circular or catalogue, or if the seed is delivered by a common carrier, the farmer is considered a vendor and must comply with the provisions of the Act Seed taken to community sales for sale must be labeled in accordance with the law. Even though the farmers' seed under certain conditions is exempt from the tagging requirements it is always the best plan to have such seed tested

FREE TESTING OF SEEDS

During the past year 3,069 samples of seed were tested free of charge for farmers and seedsmen. The privilege of having these tests made is of much value to the farmer and the smaller seed dealers who do not have facilities for testing seeds. Not all of the tests requested can be made promptly during the busy season from January to March. Therefore, it is important that all samples be sent in as early as possible, preferably from September to December. When submitting a sample of seed for test to the seed laboratory the following directions for securing the sample should be observed in order that the sample may represent as accurately as possible the lot from which it is taken. No matter how accurately an analysis is made it can show only the quality of the sample submitted.

DIRECTIONS FOR TAKING SAMPLES

1. The minimum weight of seed forwarded for test should be approximately:
    - (a) Two ounces (cupful) of grass seed of any kind or of white and alsike clover;
    - (b) Five ounces (cupful) of red and crimson clover, alfalfa, millet flax or seed of like size;
    - (c) One pound (pint) of cereals or seed of like size.
2. Samples may be drawn:
    - (a) With seed triers;
    - (b) With long stickers;
    - (c) By hand, taking approximately equal parts of the sample from at least three different places in the sacks, including the top and opposite sides as near the bottom as practicable.
3. Samples should be drawn from each bag when there are not more than five bags in the lot, from every fifth bag when there are more than five bags but never from less than five bags. All samples so drawn should be combined into one composite sample.

DIRECTIONS FOR MAKING GERMINATION TESTS AT HOME

Satisfactory germination tests may be made of the larger field seeds at home, leaving the laboratory facilities of the Agricultural Experiment Station available for the grasses and clovers which are more difficult to analyze.

The seed to be germinated should be mixed thoroughly and the required number of seeds (100 seeds of grains and 200 of clovers and other small seeds) counted out just as they come.

The plate germinator is satisfactory and very simple to operate. The seeds to be germinated are placed between two thicknesses of folded blotting paper or cloth (heavy grade of muslin or canton flannel). This should be moistened and placed between ordinary tin or porcelain plates and kept in a warm room where the range in temperature is from approximately 85 degrees during the day to 65 degrees at night. The place selected for the test should not be too near a window, stove or register.

The time required for germination tests varies with different kinds of seed. Under favorable conditions grass and clover seeds begin to sprout in three or four days. The tests should be continued for ten days or two weeks. Every two days the tests should be examined and a record made of the number of seeds that have sprouted. Also the blotting paper or cloth must be kept sufficiently moist. The number of seeds which germinate out of the 100 seeds will give the percentage of germination. *However, those seeds which develop weak sprouts should not be counted because they may not continue their development into normal plants.*

FILLING OUT OFFICIAL INDIANA LABELS

PURITY

The minimum purity means the percentage of pure seed of the kind and variety given on the official label. Statement of purity as 97 per cent including two per cent crop seeds, or 95 per cent and two per cent crop seeds, will not be permitted. In cases where the seed contains two or more kinds of agricultural seed, each present in excess of five per cent, the seed mixture should be labeled with the official green colored mixture label, Style C.

The filling out of the column "per cent of seed" on the mixture label can be explained best by an example. For instance if a mixture is composed of 60 per cent Kentucky Blue Grass with a purity of 80 per cent and 40 per cent of Red Top with a purity of 90 per cent, the per cent of Blue Grass should be given as 48 per cent, obtained by taking 80 per cent of 60. The Red Top should be given as 36 per cent, obtained by taking 90 per cent of 40.

The percentage of purity of the large seeds such as soybeans, corn, wheat, vegetable seeds, etc., must be stated on the official label the same as for any other seed.

GERMINATION

The term minimum germination means the percentage of sprouts obtained in the prescribed time for the test. If the seed contains hard seeds this percentage should be stated after the term "hard seed" on the official label. In no case should the sum of the percentages of sprouts and hard seeds be given as the percentage of minimum germination. Hard seeds are those seeds which remain hard at the end of the germination test. Such seeds due to an impermeable seed coat fail to absorb water and produce sprouts.

Distributors should not ship seed until the germination test is completed. The statement "In Test" on the official label does not meet the provisions of the seed law. If there is a demand for the seed the dealer may be tempted to sell the seed before he receives a report on the germination, thus placing himself liable to prosecution.

NOXIOUS WEED SEEDS

The number per pound of each of the noxious weed seeds present in the seed must be listed on the reverse side of the tag irrespective of the number present. The term "trace" is not permissible. The statement of the noxious weed seeds in terms of proportion will not be permitted. Those weed seeds listed as noxious in the Indiana Seed Law may be found in Table 5 on page 12.

PLACE WHERE GROWN

The official Indiana tag must give the name of the state, territory or foreign country where the seed was grown. Terms such as Domestic, U. S. A., Northwestern, and Central States do not meet the requirements of the law, and seed found so labeled will be removed from sale immediately until the tags have been corrected.

The following statement relating to the adaptability of clover seed of different origins is taken from the Report of Progress of the Soils and Crops Experiment Farm conducted by the Department of Agronomy:

"Clover seed produced from native strains in Indiana, Ohio, and probably other central corn belt states, Colorado seed, and the Tennessee disease resistant strain are well adapted to Indiana. Seed from other northern states and Canada is almost as good, although second growth has been considerably less in the tests so far conducted. Seed from Oregon is undesirable, being decidedly less winter hardy. In the tests conducted at Lafayette the Oregon clover has winter-killed an average of 22.5 per cent as against 10.2 per cent in seedings from home-grown seed. Clover from central and north central Europe, except Russia, winter-kills from one-fourth to two-fifths and is very decidedly lacking in ability to make a satisfactory second growth. The lots of Russian clover tested have been quite winter hardy, although the plants are smaller, particularly in the second growth, than native clover. Seed from southern Europe is entirely unfit for use in Indiana. Seed from Chile is also unadapted to Indiana.

"Foreign clover seeds may be of good quality and produce good stands of plants, but when it comes to winter hardiness and yielding ability they cannot be judged by the appearance or germinating quality of the seed. Dealers as well as farmers should bear this in mind and make proper distinction."

STAINED SEED

The Federal Seed Act prescribes that all imported red clover seed of unknown origin and that from Italy must be stained ten per cent red; all from Canada one per cent violet and all other imported red clover seed of known origin one per cent green.

All imported alfalfa seed of unknown origin and that from Africa must be stained ten per cent red; all from Canada one per cent violet; all from Turkestan ten per cent purple-red; all from South America ten per cent orange-red and all other imported alfalfa seed of known origin one per cent green.

CERTIFIED, VERIFIED AND AFFIDAVIT SEED

Certified seed is seed the purity, germination, and variety of which is certified to by some state certifying agency or an agency closely associated with some state office or department. The seed is shipped in sealed sacks with a certified seed tag attached. During the growing season the fields are inspected to ascertain trueness to variety of crop, and after the harvest the seed is tested to determine whether it meets the prescribed standards of the certifying agency. In Indiana the Indiana Corn Growers' Association certifies corn, wheat, oats, lespedeza and soybeans. The State Entomologist in coöperation with the Purdue University Agricultural Experiment Station certifies tomato seed. The other most commonly certified seed found in the state is Grimm Alfalfa.

Verified-Origin seed is seed the origin of which is attested to by certain seed dealers under supervision of the Government. Seed verification service deals with origin only, meaning Place Where Grown, and gives no guarantee as to the variety, purity or viability of the seed. At the present time red clover and alfalfa are the only seeds verified as to origin. Verified seed is tagged with tags bearing the official verification emblem.

Affidavit Grimm is alfalfa seed for which the grower has made affidavit as to its being Grimm Alfalfa. This affidavit seed is not regulated by either State or Federal Government.

ATTENTION DISTRIBUTORS, DEALERS AND TRUCKERS

If seeds such as oats and soybeans are sold for seeding purposes they come under the provisions of the law and must be tagged with Indiana seed tags. It is not proper to say that the oats or soybeans are being offered for sale as feed oats or feed soybeans and thereby attempt to evade the seed law when these seeds are actually being sold for seeding purposes. The mere fact that the dealer or trucker says that he is selling his oats and soybeans as feed when it is generally known and he himself as well knows that they are going to be used for seed does not in any way relieve him from the responsibility of complying with the seed law by properly tagging the oats and soybeans with official Indiana Seed Tags.

The retail seedsman's attention is again called to the fact that it is necessary to fill out additional Indiana seed tags from the tag furnished by the wholesale seedsman and attach a sufficient number of them to the seed to cover its net weight before offering or exposing the seed for sale.

ATTENTION PURCHASERS

The seed purchaser should be careful not to be misled by the offer for sale of seed at abnormally low prices. Reliable dealers go to an expense to assure the correctness of their representations and it is natural that they should be compensated for this care. The buyer should insist that the seed be properly tagged with Indiana state tags. All tags, correspondence and records pertaining to seed purchases should be saved until the buyer is satisfied that the seed he received has met the desired qualifications. Any irregularities should be reported to the State Seed Commissioner. If the case appears to violate the Federal Seed Act the State Seed Commissioner may report the matter to the Division of Seed Investigations, Bureau of Plant Industry of the United States Department of Agriculture.

The Indiana Seed Law does not prohibit the sale of inferior seed when such seed is tagged correctly. For this reason the purchaser should always read the information stated on the tag before buying his seed. Failure to purchase good quality labeled seed may result in poor stands, undesirable varieties and infestation of the soil with noxious weed seeds.

It is unwise to purchase seed from a trucker or a stranger whose reputation is not known. Buyers should also beware of cheap seed advertised by out-of-state so-called "bargain" seed houses. Such seed is usually not tagged and is shipped in small lots directly to the consumer.

The farmer will find that it is to his advantage to buy seed from a reliable seed dealer. Table 8 entitled "Summary of Seed Inspection, July 1, 1935, to June 30, 1936," may be of considerable value to seed purchasers in that it shows just how careful the different seedsmen were in tagging their seeds and also in maintaining the claims on their tags.

Table 1 shows that in general there has been a continued improvement in the correct labeling of seeds in the last few years. A careful survey of the samples listed as seriously misbranded in 1936 reveals some interesting data. Those kinds of seeds seriously misbranded in germination consist mostly of corn, sweet clover, red top, blue grass and lawn grass mixtures while those seriously misbranded as to noxious weed seeds include Korean lespedeza, red clover, red top, timothy and lawn grass mixtures. Fifty per cent of all official samples of lawn grass mixtures were found to be seriously misbranded in some form or other. These mixtures are usually composed of the so-called temporary grasses and contain entirely too much chaff and weed seeds. Curtailment of these inferior mixtures would benefit the general public and the dealers in high-class mixtures.

Examination of Tables 2, 3, 4, 5 and 6 shows a marked improvement in the quality of the seed offered for sale but the quality of much of the seed could be increased a great deal by more thorough cleaning.

Table 8 gives in detail the results of the analyses of 1,362 official samples.

TABLE 1—Progress in Seed Inspection

YEAR	Number of Samples Examined	Number Seriously Misbranded	Per Cent Seriously Misbranded
1925	745	271	36.4
1928	969	289	29.6
1929	1,230	403	32.7
1930	1,044	184	17.6

Circular No. 226 November, 1936

ELECTRIC SOIL HEATING FOR HOTBEDS

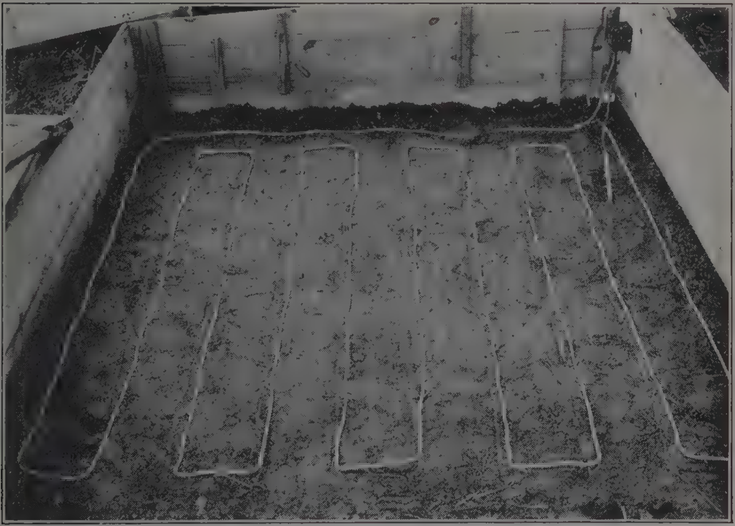

Fig. 1. Showing arrangement of cable and thermostat in a 6- by 6-foot hotbed, which is a practical size for the production of early vegetable plants and flowering plants. The cable is covered by 3 to 4 inches of garden soil and the temperature is automatically controlled.

PURDUE UNIVERSITY
AGRICULTURAL EXPERIMENT STATION
LAFAYETTE, INDIANA

SUMMARY

1. The use of soil-heating cable for heating hotbeds electrically is superior to the individual heater from the standpoint of ease and cost of installation, and cost of operation.
2. Cabbage and tomato plants will germinate in less time and the plants grow faster in hotbeds with the cable installed on the surface of the soil or in the soil and air or at a depth of 3 inches in the soil than in those where the cable is 6 inches below the soil surface.
3. Records of 35 electrical hotbeds operated in Indiana from 1931-36 showed a variation in consumption from 0.22 to 3.60 kilowatt-hour per 3- by 6-foot sash per day. Of the entire group, 8 used less than 1.0 kilowatt-hour per sash per day, 12 used from 1.0 to 1.5, 7 used from 1.5 to 2.0, 4 used from 2.0 to 3.0, and 4 used more than 3.0.
4. Covering hotbeds at night reduced the amount of energy consumed and the use of cinder insulation under and around the beds showed a saving of 20 per cent in amount of electricity used. Banking the frames with soil and fitting sash tightly to the frames likewise reduced energy consumption.
5. Control of heating units with thermostats showed no advantage in saving of electric energy over manual control, but eliminated the necessity for close personal attention to temperature regulation.

ELECTRIC SOIL HEATING FOR HOTBEDS

T. E. HIENTON, Dept. of Agricultural Engineering
J. H. MACGILLIVRAY, Dept. of Horticulture

Interest in heating hotbeds and cutting benches with electricity has increased rapidly because the amount of fresh horse manure available for supplying heat has decreased and because satisfactory electrical heaters have been developed to replace manure. Studies have been conducted in Indiana since 1931 to determine the practicability of different types of electrical heating units, the economy of their use in comparison with other sources of heat and the quality of plants produced.

The first use of electric heat for hotbeds is reported to have occurred in Norway in 1922. A device of this type was first used in the United States in the State of Washington in 1925. Professor Garver of Washington State College installed the first experimental electric hotbed in 1927. Heaters used were of home-made construction until 1931 when the first commercial unit heaters and soil-heating cable made their appearance.

Investigational work with electrical heating of hotbeds and cutting benches was initiated in Indiana in 1931. Three hotbeds, of two 3- by 6-foot sash each, were installed, using various types of insulation around the frames. One-half of each hotbed was heated with individual heaters and the other half with lead-covered resistance wire. In the cable-heated hotbeds, 83.3 per cent of the tomato seeds were germinated, in those with unit heaters, 79.5 per cent, and in a check steam-heated hotbed, 69.4 per cent. This difference was apparently due to the more nearly uniform soil and air temperatures in the electric than in the

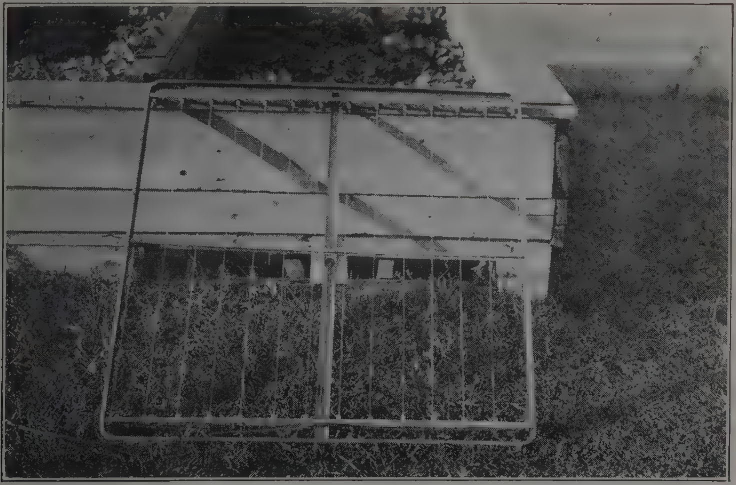

Fig. 2. The underheat type of electric heater is used in hotbeds and cutting benches. Each unit is usually provided with an individual thermostat.

steam-heated hotbed. Results of this study disclosed that the cable was superior to the individual heater from the standpoint of ease and cost of installation, and cost of operation.

Ten electrically heated hotbed and two cutting-bench test installations, using soil-heating cable to provide heat, were made during 1932 and records obtained of their operation. A need for additional information on the proper depth and lateral spacing of the cable was disclosed from observations of these installations. A study to determine the optimum depth and lateral spacing of the cable in hotbeds was made during 1933 and 1934 by G. W. Alkire, a graduate student, on two crops, cabbage and tomato. One phase of this study was made with cable spaced 7 inches apart at depths of 6 inches, 3 inches and flush with soil surface. The second phase of the study was conducted with the cable installed 6 inches deep with lateral spacings of 7 inches, 10 inches, 14 inches and 18 inches. An installation of cable spaced 14 inches apart, 6 inches deep, with 30 additional feet of cable fastened to the frame 3 inches above the soil, was also included.

Results of these studies, listed in Table 1, showed that cabbage and tomato seeds will germinate in less time and the plants grow faster in hotbeds with the cable installed on the surface of the soil or in the soil and air, or at a depth of 3 inches in the soil than in those where all of the cable was placed 6 inches below the surface of the soil.

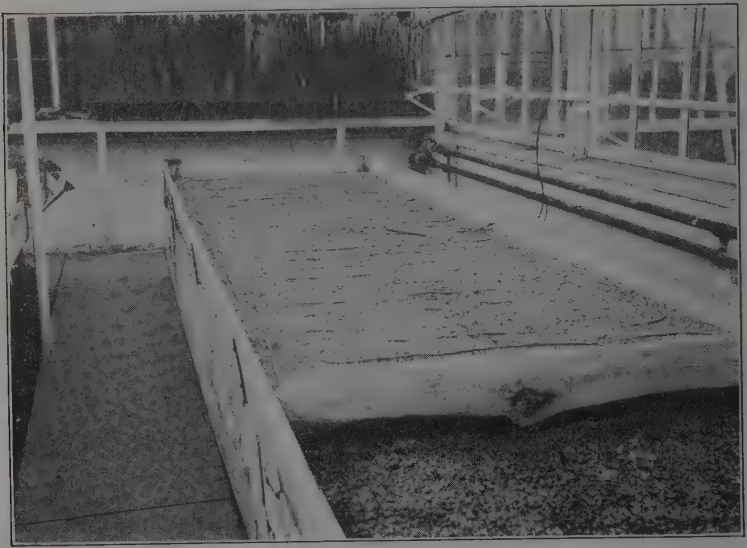

Fig. 3. Electrically heated cutting bench in which cable is laid 7 inches apart. The sand for cuttings is placed on the cable.

Air temperatures varied more widely than soil temperatures in hotbeds with cable at a depth of 6 inches than in the others included in the study. Air temperatures dropped as low as 40 degrees F. at 6 a. m. in the hotbeds

Table 1. The effect of different lateral and depth spacings upon electric consumption and the growth of cabbage and tomato plants.

[1] 30 feet of cable, fastened on sides of frame 3 inches above soil, 30 feet in soil.

[2] 5.5 watts in soil, remainder in air.

[3] Number of kilowatt-hours for each degree rise of the air temperature or soil temperature in the hotbed, above the outside temperature, per sash per day.

with lateral spacing of cable of 18 and 14 inches respectively, at 6-inch depth, with outdoor air temperature of 32 degrees F.

Energy consumption per sash per day increased in electrically heated hotbeds as the lateral spacing of the cable decreased and as its depth decreased with the same lateral spacing. The amount of electricity consumed to produce one degree F. rise in soil temperature above outside air temperature was greater where all or a part of the cable was installed on the surface of the soil or in the air than where laid in the soil. However, higher air temperatures were maintained in the former type of installation than in the latter.

*Power was on continuously.

was made in 1931 by M. W. Richman as his undergraduate thesis in Horticulture. Results of his work are shown in Table 2. His conclusions were that, while temperatures of 75 to 80 degrees F. gave quickest rooting, those from 70 to 75 degrees were more satisfactory for coleus, considering cost. The roots on cuttings propagated in mixed sand and peat moss were larger, longer and more abundant. The best propagating conditions were obtained with high humidity surrounding the plants and fairly low moisture in the sand.

Electric heat was used experimentally during 1933, 1934 and 1935, 2 to 3 inches beneath rows of celery, by a grower near Fort Wayne. The difference in rate of growth of heated and unheated plants in 1933 is evident in Figure 4. Increases in yield of 61.8 per cent, 83.4 per cent, 33.6 per cent and 32.9 per cent were produced in 1933 with cable wattages per foot of 9.7, 6.7, 4.3 and 2.4, respectively. However, during each of the three years used, the cost of electricity at 2 cents per kilowatt-hour has exceeded the value of the additional celery produced at 10 cents per pound.

Records on a total of 35 hotbed installations and 4 cutting benches, obtained from 1931 to 1936, are listed in Table 3. The hotbed installations included a total of 644 sash, 3 by 6 feet in size, and the cutting benches, 393 square feet. Hotbeds varied from the 2-sash 6- by 6-foot size used by the city

Table 3. Records of operation of electric hotbeds and cutting benches in Indiana, 1931-36.

*Per 3- by 6-foot sash per day.

gardener for raising his vegetable and flower plants, to 16-sash units for raising tomato plants for canning factory or market gardener (Figure 5), and to 50-sash units for growing sweet potato plants in southern Indiana (Figure 6).

Results reported by those using electrical heating in hotbeds indicate that seeds germinate faster and with a higher percentage than in manure- or steam-heated ones. One grower reported that tomato seeds planted in an electric hotbed germinated in six days, but required sixteen days in a manure-heated one. Another reports 58 per cent more sweet potato plants from an electric than from a manure-heated hotbed. The tomato plants shown in Figure 5 which were raised in the electric hotbed, on the left, yielded 10.4 tons per acre, while those heated in the steam hotbed on the right yielded 9.4 tons per acre. A central Indiana grower, who raises plants for retail sale, produced 3,750 plants per bushel of sweet potato seed in an electric hotbed

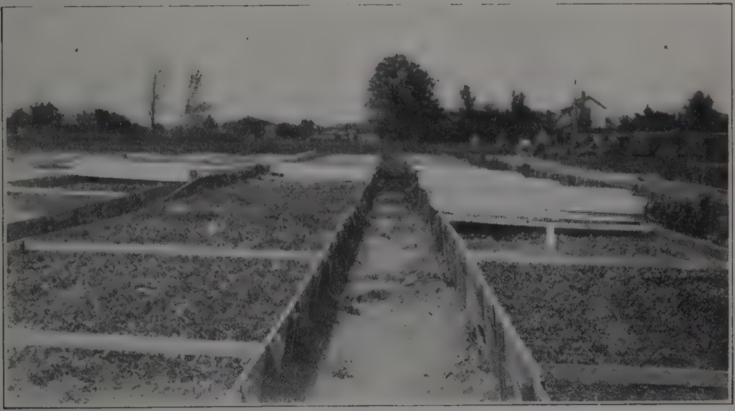

Fig. 5. The relative size of tomato plants produced by electric and steam heat. The stakes are of equal height above the ground. The electric bed is on the left and these plants produced 10.4 tons of tomatoes per acre as compared to 9.4 tons for the steam-heated plants.

and 2,334 per bushel in one heated by manure. The plants returned $14.25 and $8.16 per bushel of seed, respectively, when grown in electric- and manure-heated hotbeds, the difference being due in part to the earliness of the plants in the first type.

COST OF OPERATION

The records obtained on 35 electrically heated hotbeds and four cutting-bench installations (Table 3) during the past six years report the consumption per sash per day while heat was used. The wide variety of methods used in building and insulating the hotbeds, combined with a wide difference in operating temperatures maintained in them, resulted in a considerable range in consumption. A use of as low as 0.22 kilowatt-hour per 3- by 6-foot sash per day and another of as high as 3.60 was reported. Of the entire number, 8 used less than 1.0 kilowatt-hour per sash per day, 12 used from 1.0 to 1.5, 7 used from 1.5 to 2.0, 4 used from 2.0 to 3.0 and 4 used more than 3.0. Experience gained in the first season in operating electric heaters in hotbeds enabled several growers to reduce the consumption nearly 40 per cent during the second year.

Consumption of electric energy in cutting benches varied from 0.92 to 1.74 kilowatt-hour per square yard per day. These amounts were all less than that found by Richman to produce the most satisfactory cuttings from coleus, where cost was considered. This smaller consumption is most probably due to higher greenhouse air temperatures than that which prevailed during the test at Purdue University.

Covering hotbeds with canvas strips, straw mats or other covering at night reduced the amount of energy consumed and the use of cinder insulation under and around the beds showed a saving of 20 per cent in amount of electricity used. Banking the frames with soil and fitting the sash tightly to the frames likewise reduced energy consumption. Control of heating units with thermostats showed no advantage in saving of current over manual control, but eliminated the necessity for close personal attention to temperature regulation.

ELECTRIC HEATING SYSTEMS

Two types of hotbed heaters are included in Table 3, the underheat type, Figure 2, in which the heaters are placed in compartments beneath the hotbed soil, and the direct type, Figures 1 and 6, wherein the soil is heated by direct contact with lead-covered cable.

The underheat method may be used to heat a hotbed and a cutting or propagating bench in a greenhouse. Such heating elements are composed of resistance wire supported by metal frames approximately 30 inches square and are usually provided with a thermostat.

The direct method which utilizes hotbed-heating cable is used extensively in outside hotbeds, in cutting and propagating benches, and outdoor plots. It was used in all installations reported in Table 3 except one in 1931. Hotbed-heating cable consists of a small resistance wire insulated with asbestos or other materials and enclosed in a flexible lead sheath. This type of heater is best suited to large installations, while the underheat type is practical only for small hotbed installations of a few sash or small areas in greenhouse benches.

COST OF EQUIPMENT

The heating cable will cost approximately 6.25 cents per foot, resulting in an investment of $1 to $2 per 3- by 6-foot sash, depending upon the spacing of the cable used and the size of the installation. Thermostats will cost from $6 to $9. Individual heaters for each sash cost approximately $10 each, including thermostat.

The cost for heating equipment for a 6- by 6-foot hotbed with cable 7 inches apart (Figure 1) will amount to $3.75 for 60 feet of cable plus a thermostat costing $7.50. Heating equipment for a 40-sash hotbed will cost $45.00 for cable and will require two thermostats, with the cable spaced 12 inches apart.

Hotbeds are used primarily for plant production and plant forcing either in addition to a greenhouse or by persons not having greenhouse facilities available. Their use is one of the most economical methods of producing desirable plants out of the normal growing season which are brought to maturity in the garden or field. Hotbeds may be used also as cold frames after the heat has been used up from the manure-heated or turned off from the steam or electrically heated beds. Cold frames are valuable in hardening off plants so that they may better withstand any unfavorable weather after transplanting to the garden. Hotbeds may also be used to grow such quick-maturing crops as radishes and lettuce. These may be grown in early spring or in the fall and, since they are cool season crops, little heat is required.

LOCATION OF BEDS

Several of the important considerations relative to the location of hotbeds are as follows:

1. Easy accessibility to house or farm buildings for ease in care.
2. A well drained soil permits a more effective control of soil moisture in the hotbed.
3. A good water supply.
4. Good protection from the wind by means of building, hills or windbreaks.
5. Single rows of sash should extend east and west and the sash slope to the south to obtain maximum amount of sunlight.
6. Where there are several beds, there is need of ample space to permit easy access to them.

CONSTRUCTION

Cinder insulation has been used by some Indiana growers on the sides or bottom or both of their electric hotbeds. Such insulation has shown approximately 20 per cent saving where used on both sides and bottom, while somewhat less saving was shown where bottom insulation only was used. Depth of cinders ranged from 6 to 12 inches on the bottom and 4 to 6 inches on the sides of the hotbeds. Satisfactory results have been obtained without using cinders or other insulation, but bed frames should be set into the soil, if possible, and banked to the tops with soil or other material to prevent heat losses.

Hotbed frames are usually in 6-foot widths and any multiple of 3 feet in length, in order to accommodate the standard 3- by 6-foot sash. Melon and sweet potato growers in southern Indiana frequently use a 4- by 10-foot sash. The frame material may be either wood, preferably 2 inches thick, or concrete. In constructing the frame, it is important to avoid cracks between the joints or around the edges of the sash, as drafts increase the consumption of electricity. The frame should be just high enough to provide sufficient space between the surface of the soil in the bed and the sash for the plants, as less heat will be required and a smaller part of the bed shaded. The rear board of the hotbed frame should be 4 to 6 inches higher than the front board.

A covering over the sash, as shown in Figure 7, during the cool nights of early spring and late fall will reduce the energy consumption of the bed considerably. Straw mats, old blankets, canvas, or tough waterproof paper which has been reinforced with sisal or other strengthening material may be used for this purpose.

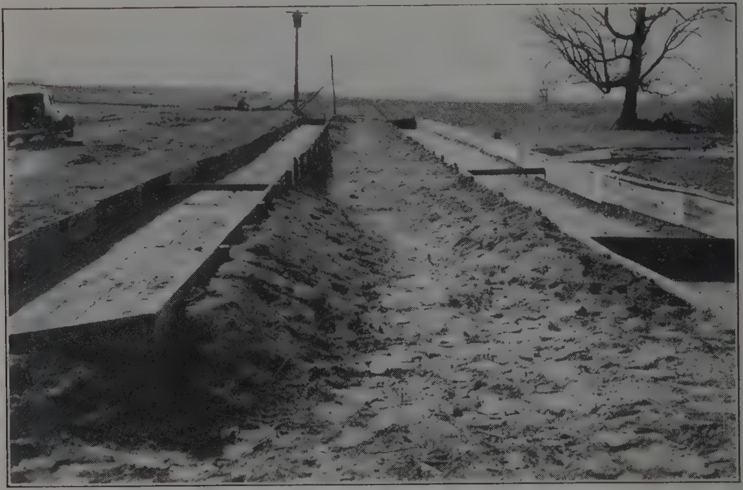

Fig. 6. A large installation of electric heating cable. Six sections of cable are placed lengthwise of the bed.

Glass sash is ordinarily used for hotbeds, although cloth or a glass substitute can be used. If greater detail of hotbed construction and management is desired, Circular Number 77 of the Purdue University Agricultural Experiment Station should be requested.

PREPARATION OF SOIL

In growing plants a soil of good texture and fertility should be used. Composted soil of sod and manure are frequently employed, but any fertile soil containing ample humus and fairly free of weed seeds may be used. Commercial fertilizer may be used to increase the plant food content of the soil at the rate of one-eighth to one-quarter pound per sash of such analysis as 2-12-6. The analysis of fertilizer used will vary with the soil. Where soil becomes infected with soil-borne diseases, it will be necessary to replace it with uninfected soil or sterilize the soil in the beds.

INSTALLATION

The installation of the element used in the underheat method usually involves the construction of a special compartment beneath the hotbed soil, as may be seen in Figure 2, while the installation of hotbed-heating cable requires no special construction.

Spacing of the cable may vary from 7 to 14 inches laterally and from the soil surface to 6 inches beneath the surface in depth. Installations for raising sweet potato plants have been found very satisfactory with the cable spaced at 12-inch intervals, 2 to 3 inches beneath the potatoes. Cable installed in cutting benches is usually laid 7 inches apart, as shown in Figure 3.

The length of cable used per 3- by 6-foot sash depends upon the wattage desired. Ordinarily, the cable is installed so as to deliver from 150 to 200 watts per sash. Sixty feet of number 19 cable will furnish approximately 400 watts at 110 volts, while 120 feet will furnish 800 watts on 220 volts. The installation of 60 feet of cable in a 6- by 6-foot area, spaced at 7-inch intervals, is shown in Figure 1. A similar method is used for 120 feet to be operated on 220 volts and used on a 6- by 12-foot or 6- by 15-foot area. Larger areas may be heated by duplicating these installations or as shown in Figure 6, where full 120-foot lengths have been laid and electrical connections made at each end. Hardware cloth may be used in the soil 1 inch above the cable if there is danger of injury to the lead covering from tillage tools.

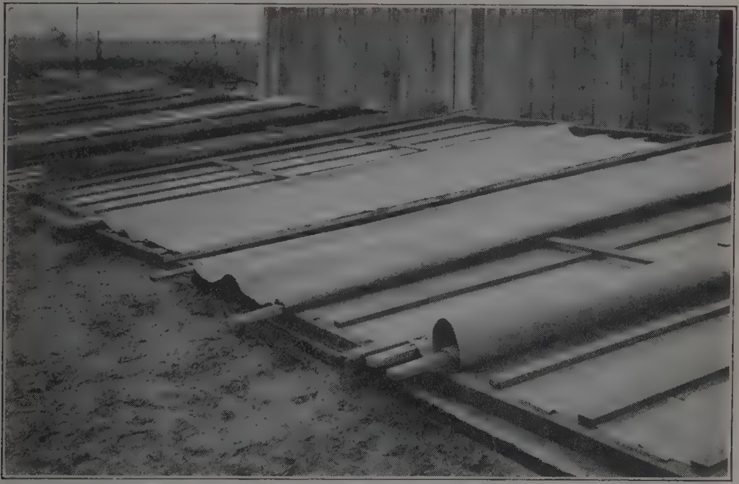

Fig. 7. Conservation of heat by means of coverings on cold nights and tight-fitting frames reduces the consumption of electricity.

The wattage from a given length of cable is dependent upon the resistance of the wire (ohms) and the voltage to which it is connected. The following formula is used in computing wattage:

$$\text{Watts} = \frac{\text{line voltage}^2}{\text{total ohms in cable}}$$

For a 110-volt circuit and 60 feet of cable with a resistance of 0.5 ohm per foot, the wattage is:

$$\text{Watts} = \frac{110\text{x}110}{60\text{x}0.5} = 403$$

The length of cable to use in order to secure a desired wattage can be computed from the following formula:

$$\text{Length, in feet} = \frac{\text{line voltage}^2}{\text{watts x ohms per foot}}$$

Assuming it is desired to heat a 2-sash hotbed with 400 watts, using cable with a resistance of 0.5 ohm per foot, on a 110-volt circuit, the number of feet of cable can be calculated by substituting in the above formula, as follows:

$$\text{Length, in feet} = \frac{110\text{x}110}{400\text{x}0.5} = 60$$

The minimum number of feet of cable that should be connected directly to the circuit is usually specified by the manufacturer. Since the wattage per foot of cable increases as the length of the cable decreases, it is possible that the cable may be damaged by excessive heat if too short a length is used.

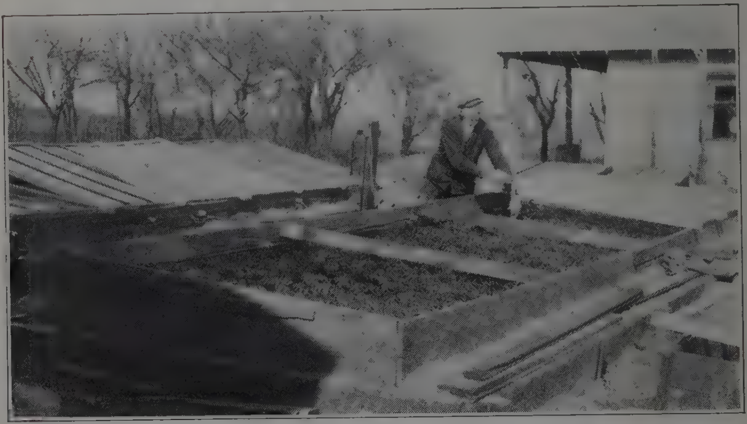

Fig. 8. Electric hotbed used for home production of early tomato plants either for the market gardener or for sale to home gardeners. Spring production of vegetable, flowering, and bedding plants is often a profitable business.

HEAT CONTROL

Automatic temperature control is secured by the use of a thermostat. Hotbeds may be operated satisfactorily and economically by using a manually operated switch, but a thermostat will reduce the amount of supervision necessary in order to maintain the desired temperatures and will also frequently result in a saving of electricity, particularly on warm days. A thermostat with a capacity of 15 amperes will regulate a maximum load of 1650 watts on a 110-volt circuit or twice that amount on a 220-volt circuit.

Thermostats used in Indiana installations have all been of a bulb and bellows type which quickly makes or breaks the circuit to the heaters. Regardless of type, any satisfactory thermostat should quickly open or close the circuit to prevent radio interference and burning of thermostat points.

HOTBED TEMPERATURES

Plants are classified into warm- and cool-season crops, and there is a difference in their temperatures for optimum germination and growth. Cool-season crops, such as cabbage, cauliflower and lettuce, will germinate at 50-60° F., while warm-season crops, such as cucumbers, tomatoes and peppers, will germinate more satisfactorily with a temperature of 70-75° F. The night temperature during germination may be carried 5-10° lower. After the appearance of a majority of the seedlings, the temperatures may be lowered as follows: 40-45° F. day or night for cool-season crops; and 55-60° F. for warm-season crops in the daytime and as low as 50° F. at night. Temperatures on cloudy days may be the same as those during the night. Sweet potatoes should be bedded in a soil which can be maintained at a temperature of about 70-75° F. After the plants have begun to appear, a lowering of the temperature to 60-65° F. is preferred by some growers. These temperatures are considered favorable for sweet potatoes, but lower temperatures may be used where a slower growth is desired.

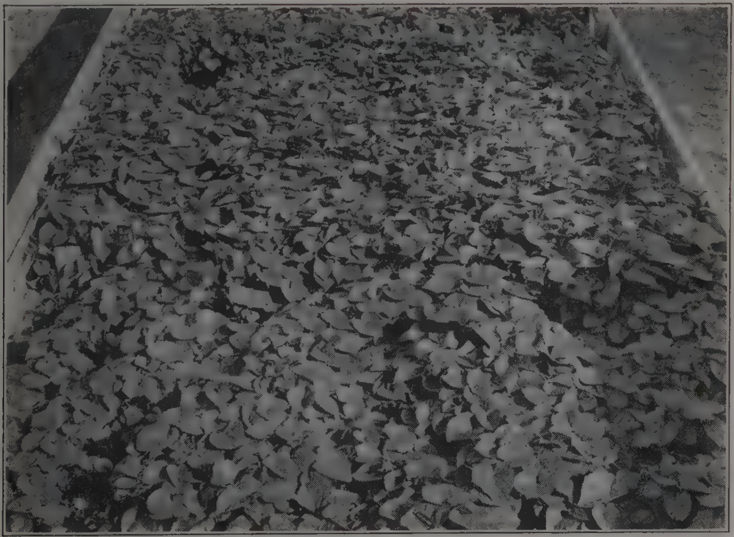

Fig. 9. Excellent sweet potato plants grown in hotbed heated by electric cable on the sides as well as in the soil.

Temperatures can be controlled by regulation of the artificial heat or by ventilation through raising and lowering the sash. Daily ventilation will assist in producing sturdy, stocky plants.

OPERATION

Watering should be carefully performed, as it is one of the methods used in controlling plant growth. Water should be applied in sufficient quantity to soak the soil thoroughly rather than frequent light waterings. It is best to water during the late morning or the middle of a sunny day so the foliage of the plants is dry by night. In other words, water when the hotbed temperature is rising rather than falling. Careful watering will assist in the prevention of the spread of disease.

The water requirements of the electric bed are practically the same as the manure-heated bed except in installations where the soil is underlaid with cinders, in which case more water will be necessary due to the greater drainage.

Electrically heated hotbeds require less ventilation than manure-heated beds because of the lack of ammonia fumes, vapor and uniformity of heat. Practically the only time ventilation is needed is on warm, bright days.

The use of electric heat in plant growing has steadily increased in Indiana for five years. There will be a further increase in use by present operators as well as new installations as growers become familiar with its advantages for plant production.
